The following smart review of the Autobiography of the late Sir Benjamin C. Brodie, from the 'Journal of Mental Science' will be read with interest:—The son of a rector, magistrate, and deputy-lieutenant, enjoying the intimate acquaintance of a leading whig lord; whose mother was the daughter of a wealthy banker, and inherited 10,000*l.* soon after her marriage; whose aunt married Dr. Denman, and whose first cousins married Dr. Baillie and Sir Richard Croft, three eminent physicians in London; who, moreover, had an elder brother studying for the bar at Lincoln's Inn, as also a cousin; could not with reason deplore his fate when it was decided for him that he should leave his father's home to study in London for the Medical Profession. His education had been liberal; his training good. Accustomed to diligent exercise of his mind in the attainment of general knowledge under the tuition and guidance of his father, in London he would have to continue the same industry in acquiring special knowledge under the tuition and guidance of friends and relatives engaged in that profession to which he was about to belong. He would exchange a small domestic circle for a large one of friends and kindred not closely allied to him. He had hitherto encountered no great difficulties, and he had no reason to anticipate them in the future. Amongst Medical worthies of every age there cannot be mentioned one who started on his career with such substantial advantages as Sir Benjamin Brodie possessed when he "first came as an adventurer to London." Position, power, and influence, were available on all occasions to promote his interests, and the best advice was always at hand to guide his every step. Had he been possessed of ordinary talent failure was impossible; with his rare combination of admirable qualities, success was certain.

Success is always interesting to read about; the autobiography of a successful man being only eclipsed in interest

by that of a great failure. The autobiographer is necessarily egotistic, and, to some extent, subjective; his opinions concerning himself, however, are valuable aids to a just criticism of him. For we see him as he saw himself, and we see him as he appears to us. As he acquaints us with his feelings in the details of life, and in the hard struggle how physically to exist, we see in these purely personal matters the real character of the man displayed more clearly than in his conduct before the world. Judging from Sir Benjamin Brodie's autobiography, we are inclined to consider prudence to have been his characteristic virtue; and his possession to such a degree of this eminently northern quality goes far to confirm the truth of his supposition that he was of Scottish origin. His frequent allusions to money matters; the very moderate demands he made on his father's "limited means;" and, after his father's death, his endeavours, by avoiding all extravagance, to live comfortably and keep up a respectable appearance on means less than those of many of his acquaintances, who were, notwithstanding, frequently in difficulties, manifest the economical and cautious cast of his mind. When he married, his income was 1530*l.* a year, and his *naïve* remark that his wife and he "managed, by being careful as to their mode of living, to make both ends meet at the end of the year," and his reference to the considerable anxiety caused by his having an additional person to keep, are more calculated to create a smile than to excite sympathy with him in his distressing position. One may form an opinion of the magnitude of the trials, and the nature of the difficulties with which Sir Benjamin Brodie had to contend through life, when we find that to have to maintain a wife on 1530*l.* a year, with brilliant future prospects, produced dyspepsia, which troubled him for two or three years. A rapidly increasing practice removed his anxieties, and cured his dyspepsia.

It must not be forgotten, however, that although Sir Benjamin Brodie had such a good start and so many helps on his way, half his success was due to his own industry sobriety, tact, and good common sense. The exercise of the same solid qualities would have ensured success in whatever circumstances he had been placed at the outset of his career, but they never would have elevated him to the position which he occupied. Fortune was very kind to him, and he made the best use of her favour.

It was in the autumn of 1801 that young Brodie first came to London "to grope his way as well as he could by himself," in the profession for which he was destined. During his first winter he attended Abernethy's lectures on anatomy, of whom he speaks in terms of the highest praise. His admiration for this distinguished teacher led him to follow his footsteps, and devote himself to pure surgery. In the dissecting-room he formed the acquaintance of Lawrence, even then a remarkable person. "From that time to the present," he says, "Lawrence and myself have been moving on parallel lines, he having had the largest share of private practice next to myself." And after criticising Lawrence as a writer, speaker, and thinker, he adds, "that he is thoroughly acquainted with his profession cannot be doubted, for it would not have been possible for him otherwise to retain for so long a period the high place which he has occupied." So widely different are such minds as that of Brodie and Lawrence, that we might, perhaps, as reasonably expect the former to sympathise with the genius of the latter, as the latter to appreciate at its full value the sagacious mediocrity of the former. We cannot agree with Sir Benjamin Brodie that an exact parallel, or, indeed, any parallel, can be drawn between him and Lawrence. That Brodie had the larger private practice is certain; that he possessed the qualifications which obtain practice in greater perfection, or with fewer drawbacks than Lawrence, may be admitted; but there can be no question that the latter has a higher order of mind, stands on a higher platform, and must be judged according to a different standard.

"Genius does what it must: talent what it can."

During his second winter in London, Brodie's professional studies were still, as in the first winter, limited to anatomy, except that by the advice of Dr. Baillie he attended a chemist's shop to gain some knowledge of materia medica and pharmacy. It was not until the spring of 1803 that he became connected with any hospital. He then entered as a pupil of Sir Everard Home (at that time, Mr. Home), at St. George's Hospital. It was the good advice of Dr. Baillie which induced him to make himself a complete anatomist before he commenced the study of diseases in the hospital, and he found it of great advantage to him. In 1805 he was appointed house-surgeon at St. George's, and his connection with Sir Everard Home was the beginning of his private practice, for that eminent surgeon proposed to him that he should take the place of his *protégé* Nicholson, who had hitherto assisted him, and who had now gone to India. About this period also Sir Everard Home introduced him to Sir Joseph Banks, president of the Royal Society, and that distinguished man invited him to the meetings which were held in his library on the Sunday evenings which intervened between the meetings of the Royal Society. There he met with visitors distinguished by their scientific reputation, the elder Herschel, Davy, Wollaston, and a host of others. This intimacy with these eminent men was of immense advantage to him; he himself says that they treated him with much kindness and consideration, and he adds: "I obtained a place in my profession which I could not have attained otherwise."

In March, 1808, when only twenty-five years of age, through the interest of Sir Everard Home, Brodie was appointed assistant surgeon to St. George's, and Sir Everard entrusted him very much with the management of his patients. Besides he was appointed, along with the other assistant surgeon, Mr. Robert Keate, to take charge of the patients of Mr. Gunning, the junior surgeon, who was attached to the staff of Lord Wellesley in the Peninsula, and to whom at that period an unlimited leave of absence had been granted in accordance with an old law of the hospital now done away with. Not long after this he obtained the sole management of these patients. Thus he had the opportunity at an unusually early age of acquiring a large experience in hospital practice, and to this circumstance he attributed much of his professional success. He devoted himself diligently to his hospital studies. He introduced the practice of giving clinical lectures, which gave him considerable reputation amongst the students of the hospital, and also served to make his own knowledge more clear and accurate, enabling him to express himself with greater facility and precision. About this time he began to think more seriously of private practice. He took a house at 22 Sackville street, and for the first time placed his name upon the door. Owing to his reputation at the hospital, his connection with Sir Everard Home, and his intimacy with several Fellows of the Royal Society, and other men of high standing, he had no difficulty in at once obtaining practice, which yearly increased, until, free from anxiety concerning himself, he found time to pursue to some extent scientific studies. He was elected a Fellow of the Royal Society, and in 1810 he gave as the Croonian Lecture a paper on the "Influence of the Brain on the Action of the Heart, and the Generation of Animal Heat," for which he was awarded the Copley medal, an honour never before obtained by so young a man. In the year 1813 he communicated a paper to the Medical and Chirurgical Society, under the title of "Pathological Researches respecting the Diseases of Joints," which was the foundation of the book which he afterwards published, "On Diseases of Joints," and which has gone through five editions. With these exceptions, Sir Benjamin Brodie has not contributed anything of importance to Medical literature. About 1814 he became a regular visitor at Holland House, and was very intimate with Lord Holland up to the time of that nobleman's death, and with Lady Holland afterwards. Holland House has in its time been of material assistance to several young men, and was doubtless of some advantage to a rising young surgeon of good reputation. In 1816, his professional income being 1,530*l.*, Sir Benjamin Brodie ventured to marry. From that time he continued his unparalleled career of prosperity, and his good fortune never left him, but carried him steadily on from one hour to another. He filled the office of serjeant surgeon, was made a baronet by Lord Melbourne, and reached the highest point in his profession.

Sir Benjamin Brodie's life was not an eventful one. The history of the most interesting part of it, from his commencement as a student in London to his marriage, if written by the most facile pen, would never be an exciting narrative. His life owes its interest, not to any remarkable freak of fortune for his special good, but to the unbroken series of favours which she so constantly bestowed upon him. He himself was in no way remarkable for any striking intellectual quality, but for an unusual combination of ordinary qualities. He is for this reason entitled to be considered a typical representative of the successful men of the world in all professions. He is an admirable pattern to any one who desires wealth, influence, and reputation — who wishes to be great in his *day* and *generation*. He worked very hard for the present, and the present abundantly rewarded him. He was essentially a man of the times, and with the times he is even now passing away. His character and his life were completely comprehensible by average intellect; the one embodied the cardinal virtues of prosperous men who object to selling themselves for lucre, but who equally object to cherishing any ideas which have not for their aim worldly success; the other is the best text-book for that part of the rising generation whose destiny it is to carry on the world's business. Patient and persevering, Sir Benjamin Brodie never wearied. Shrewd and sagacious, he avoided everything that could injure him in the estimation of the public. With considerable tact he stood well in society. Not so far gifted above his fellows as to have little in common with them, he had not to create an artificial sympathy with them and their views, and they saw no marked superiority in him that they should either envy or hate him.

The future will not remember him. His was not an universal mind. He was a practical man of the world, whose great object in early life was to attain unto a position in which he could keep himself, and after his marriage to accumulate a satisfactory fortune for his wife and children; and he fully succeeded in accomplishing his aim. And he has left behind him a short and interesting biography, the truthful nature of which some may well doubt, if they do not bear in mind that so exceptionally fortunate was Sir Benjamin Brodie's career that those circumstances which would be "trifles light as air" to ordinary mortals, were of the greatest moment to him, the sunshine of whose prosperity was never darkened by a single cloud.

CATTLE AND CHRISTIANS.

Under the above heading S. G. O. thus writes to the 'Times':—For years past I have said that cattle have been more cared for, as to their housing and general cleanliness, than Christians. Let the public now say whether or no tens of thousands of Christians are not for ever living and dying among us; we knowing well that they have not these common elements of health, which we are warned to give our cattle. When Dr. Jeaffreson, in your columns, told his typhus tale, did any dare to dispute it? Has anything the least approaching to the measures now advised for dairies been carried out in the scenes where we know typhus is destroying, and has been for years past? In every possible detail, Dr. Thudicum, under the wing of the Privy Council, proclaims a campaign against the cattle typhus, which is to penetrate and cleanse to the smallest details of cow life. How is it with the Boards of Guardians, Sanitary Boards, and Inspectors, who have charge over the health of the poor creatures who dwell in well-known typhus nests? How is it with landowners, especially that one in Norfolk, who fought the Inspector on a question of common decency, and still is said to hold his people worse housed than the cows of many a bad dairy? I thank Dr. Thudicum for having admitted that a man and a cow have alike a claim on decent cleanly shelter, pure air, and water. The Privy Council have indorsed his deliberate opinion. Typhus is among our poor, Cholera threatens them. Shall all interest run to cow-ward, no active sympathy be shown for human beings kept in the condition which insures disease? When I read Dr. Thudicum's advice as to every living and dead thing coming in contact with a sick cow, and then thought, how typhoid poor are tended, the condition of their sheds, the state of their ventilation, to what their attendants are exposed, what the air they breathe, the water they drink; I could not but ask myself, whether we have really arrived at the conclusion, that animal is more precious than human life. Sanitariums are established for cows, with veterinary surgeons armed with all power, and in all means, to try and save. Throughout the whole kingdom committees are formed, money subscribed, every available agency enlisted to protect the cow. Two sick heifers in a dairy five miles off make a sensational topic. What, I ask is being done, for the crowded, ill-fed and poisoned poor of our towns and villages? Your columns have been open to the statements of Medical men, clergymen, all the host of witnesses who tell the public where mankind live, deprived of all, Dr. Thudicum says, they should have in common with a cow. Is there anything like the interest shown for the poor of "Thompson's rents" that is shown for the heifers on any farm? The Government of the country is alive to human typhus, as existing among us, as it is to that disease which slays our cattle, but does it show the energy with regard to the former as clearly evinces about the latter? Are owners of property as keenly appreciative of the necessity for clean cottages in good repair, with all conveniences, as they are to the cleanliness and general furniture of the cowshed or stable.

ALLEGED DEATH FROM VERATRIA.

Last Thursday Mr. C. J. Carttar, coroner for West Kent, resumed an inquiry, which had been three times adjourned, into the circumstances attending the death of Mrs. Elizabeth Reeve, which, it is alleged, was occasioned by the administration of a certain deadly poison, known as veratria. We subjoin the medical evidence:—

Mr. H. R. Palmer, surgeon, of Greenwich, said that about a quarter past four on the morning of the 15th of August last, the husband of the deceased called him from his bed, and said he wished he would come immediately to his wife, who was dangerously ill, and that he then feared it would be too late. He at once accompanied the husband, and on the way to the house he asked whether the deceased had had any excitement, and her husband replied that she had, owing to her servant being about to leave her, and one of the children having jumped or fallen from the table. He also said that his wife had been seized with vomiting, and that he had sent for Mr. Hope, a surgeon, whose assistant attended about one o'clock the day previously, and administered some effervescent medicine. On getting to the house witness found the deceased lying on her back in bed, moaning, throwing her arms up, and slightly convulsed. He was told that she had just come out of a fit. She was not unconscious, but she became conscious afterwards. The deceased's husband said that the moment she took the medicine she complained of its being noxious stuff, and became worse. Witness tasted the medicine, which he found to be an ordinary saline mixture. The husband told witness that she was pregnant, and witness suggested that labour should be brought on, but the husband objected, saying it would torture her. Afterwards her pulse became very low, showing that she was fast sinking. At five o'clock he left, having a case to attend, and on returning home at nine o'clock he heard that the husband had again called at his surgery, and that the death of the deceased had then taken place.

Mr. David Hope, surgeon, of Deptford, said he was engaged to attend the deceased in her confinement about five or six weeks before her death, when she said she expected to be confined about the end of August. She then appeared in good health, but expressed a fear that she would not go safely through her confinement. He did not again see her until after her death, but was sent for the day previously. Being from home, his assistant attended the first time about noon, the second time at four o'clock, when he remained three hours with the deceased, and again later in the evening. In witness's day-book, the writing

being that of his assistant, who had since left him, he found an entry, under date August 14, and that the ordinary mixture to allay sickness, and which was perfectly harmless, had been prescribed by him for the deceased.

Dr. Cogan, of Douglas house, Maze hill, Greenwich, said that in company of his two assistants, and in the presence of the medical gentlemen already examined, and a medical gentleman named by the deceased's husband, he made a post mortem examination of the body on the 18th of August (78 hours after death). The delay in making the examination arose from the husband objecting to its taking place unless a medical man was present on his behalf. Witness found that deceased was about eight months with child, and that there were indications of labour having been going on for some time. On the left side, between the membrane and the brain, he found a clot of blood, arising from the rupture of a blood-vessel, and sufficient to cause death. That might have been occasioned by excessive vomiting.

Professor J. E. D. Rodgers, of Pentonville, said he was a surgeon and professor of toxicology. He had received a box from Dr. Cogan containing parts of the body of the deceased, with two quantities of wine, and the remainder of the mixture and powders prescribed by Mr. Hope's assistant. He found the kidneys diseased as in "Bright's disease." Different parts were subjected to a distinct system of analysis, mercury and antimony being first searched for, but there was no trace whatever of any metallic poison. In the wine he found an alkaloid, being a preparation from plants, and which gave indications of a deadly poison known as veratria, obtained from white hellebore. In the kidneys, viscera, and portions of the liver, he found the same traces in minute but clear quantities, and in the stomach the poison was in greater quantities. One-fourth of a grain of this poison would be dangerous to life, whether swallowed or taken into the system in any other manner. Half a grain would be very dangerous, and death would take place in from six to twenty-four hours. The poison was used externally for neuralgic pains. He had tested the medicines prescribed by Mr. Hope's assistant; they were perfectly pure. The poison had been absorbed into the blood of the deceased, but from the quantities traced he had no doubt that enough might be detected to cause death. The poison was not an alkaloid to be found in every surgeon's house, and was very rarely bought in large quantities—seldom more than a drachm by surgeons.

Dr. Cogan said, after hearing the evidence of Professor Rodgers, his opinion was that the poison by producing vomiting had been the cause of the rupture of the blood-vessel, and that this had been the cause of death. The case was adjourned.

REVIEW OF BOOKS.

Tension of the Eyeball: Glaucoma, &c.: Some Account of the Operations practised in the Nineteenth Century for their Relief. By James Vose Solomon, F.R.C.S., Surgeon to the Birmingham and Midland Eye Hospital. Pp. 80. London: Churchill and Sons, 1865.

After giving an historical account of the operations performed for the relief of intra-ocular tension, Mr. Solomon sets forth the theory he has devised to explain the effects of iridectomy in glaucoma. He believes that the division of the ciliary nerves, at the point where they pass from the ciliary muscle into the iris, forms an important part of the operation, and that by this proceeding a more healthy action is induced in the ciliary ganglion, which presides over the organic function of the eye. This opinion appears to be supported by the views now generally entertained with respect to the pathology of glaucoma, namely that the nerves of the ciliary vessels are intimately concerned in the symptoms constituting the malady described under that name. With the object of relieving this disease, it is well known that various operations have been devised, those best known being iridectomy, as introduced by Von Gräfe, and practised by many ophthalmic surgeons of the present day, and the division of the ciliary muscle, as recommended and practised by Mr. Hancock. Mr. Solomon's operation is one devised by himself, and it consists of an incision dividing some of the radial and other fibres of the ciliary muscle in a transverse direction, and also dividing some branches of the nerves distributed to this part from the ciliary ganglion. His opinion seems to be that the nerves of this ganglion being vaso-motor as well as sensory, their division relieves the tension which constitutes one of the principal features of glaucoma. He does not, therefore, consider that cutting out a portion of the iris is essential to the success of the operation, nor does he adopt the mere division of the ciliary muscle, as advocated by Mr. Hancock. Mr. Solomon states very clearly the nature of his operation, and the physiological laws on which it is based, and he gives a series of cases illustrative of the treatment of glaucoma and tension of the eye-ball; some having been treated successfully by medicines and diet, and others by surgical operations. Mr. Solomon's book is well worthy of the attention not only of ophthalmologists, but of the Profession in general, as it is a very thoughtful, and at the same time practical, contribution to ophthalmic surgery.

Anniversary Address delivered before the Anthropological Society of London, Jan. 3, 1865. Dedicated to the British Association for the Advancement of Science. By James Hunt, Ph. D.; F.S.A. &c., President of the Society, pp. 32. London: Trübner and Co, 1865.

In this very able address, Dr. Hunt gives a general view of the position and progress of the Anthropological Society, of the publications which it has introduced to British readers, and of the necessity of recognising anthropology, as a distinct department of science, in the British Association. There appears to be some jealousy existing between the Ethnological and the Anthropological Societies, and while the first is represented in the Geographical Section of the Association, the second is not recognised in any section, although at the last meeting in Birmingham, some papers on anthropology were read. Dr. Hunt argues that instead of anthropology being a department of ethnology, the very reverse is the case; and as to the relative number of the members of the Anthropological and Ethnological Societies, the former, he states, has very much the advantage. An attempt was therefore made at Bath last year, and has been repeated this year at Birmingham, to introduce Anthropology as a substantive Section, but on both occasions without success. The present Address was published before the Birmingham meeting was held, and was avowedly circulated to promote the advancement of Anthropology in the British Association; and although the immediate object of the Anthropologists has for the present failed, renewed efforts in the same direction will be made next year at Nottingham, and all those who are interested in the subject will find it very lucidly and learnedly handled by Dr. Hunt. Those who are still unacquainted with the scope and objects of Anthropology, will gain much useful information by the perusal of Dr. Hunt's pages.

On Epilepsy: In what Class of Cases, and under what Circumstances, may we Reasonably Hope for Cure in Epilepsy? By William Camps, M.D. Pp. 20. London: Lewis, 1865.

In this pamphlet Dr. Camps gives a practical description of epilepsy, dividing it into the symptomatic and the idiopathic kinds, and while he admits that many cases resist all modes of treatment, he thinks that drug medication and regimen are sometimes beneficial. Of all medicines he thinks that the bromide of potassium is the most efficient, and next to it, belladonna, or its alkaloid, atropia, and its salts, especially the valerianate.

Photographs of Eminent Medical Men of All Countries, with Brief Analytical Notices of their Works. Edited by T. Herbert Barker, M.D., F.R.S.E., with Photographic Portraits from Life by Ernest Edwards, B.A. Cantab. London: Churchill and Sons. September, 1865.

The present number of this series contains the photographs,

with short memoirs, of three members of our Profession who have achieved eminence, although in different capacities. The first on the list is Sir James Clark, the Physician to Her Majesty; the second is Mr. John Propert, the well-known founder of the Royal Medical College; and the third is Dr. Acland, the Regius Professor of Medicine at Oxford. All the portraits are very good, and the biographical memoirs are as usual brief and judicious.

PARISIAN MEDICAL NEWS.

PATHOLOGY AND TREATMENT OF SPINAL PARALYSIS IN CHILDREN.

A fine child, generally between six and eighteen months old, hitherto in the enjoyment of perfect health, becomes suddenly *feverish;* the fever lasts a day or a night, sometimes forty-eight hours, but seldom as much as a week, and this condition is followed by a state of *paralysis* of peculiar aspect and progress. The loss of power is at first observed in the arms and legs, but soon becomes concentrated in the lower extremities, and finally settles in one of the limbs only, paralysing the flexors or extensors, and subsequently involving atrophy of the part. Hence a series of vital disturbances, induced by impaired nutrition, protracted loss of muscular power, and predominance of the action of the muscles spared by the disease.

The above is a rough sketch of the most habitual aspect of the singular affection, to the symptoms of which Dr. H. Roger invited attention in one of the last lectures of his summer course.

Amongst the writers who have described the disease in question, under various denominations, M. Roger mentioned Kennedy in England, Heine in Germany, and M. Duchenne (of Boulogne) in France. This gentleman calls the complaint *fatty atrophic paralysis of infancy;* other observers designate it as *idiopathic infantile paralysis;* M. Roger terms it, with Heine, *spinal infantile paralysis*, because it appears highly probable that the anatomical change, of which the symptoms are the outward expression, is primarily situated in the spinal cord.

M. Roger conceives that three stages may legitimately be recognised in the evolution of the disease—viz., the initiel or febrile period; the paralytic stage in which the loss of power, at first general, manifests a tendency to become more and more narrowly circumscribed, and a period of muscular atrophy and secondary deformation of the limbs.

The professor dwelt at considerable length on the initial, or febrile stage, which sets in without any premonitory symptoms, and being sometimes extremely mild and transient, deceives the observer and misleads him as to the subsequent gravity of the case. How, indeed, can the practitioner feel justified in predicting that an attack of ephemeral fever can possibly entail serious symptoms of paralysis? We may further remark that the feverish stage is seldom witnessed by the medical attendant, who is generally summoned only when the second period has set in; but he must even then inquire with the utmost care into the existence of a feverish attack, previously to the appearance of the functional disturbances to which his attention is solicited, because a knowledge of the fact will guide him in the discrimination of the nature of the symptoms, and give him a clue to their import. Direct observation, however, or the commemorative description of the earlier symptoms, show that the feverishness set in *suddenly*, with restlessness and sometimes drowsiness and langour; the skin is hot and the pulse frequent, but the feverishness is seldom ushered in by emesis. M. Roger erases from the list of the earlier manifestations of the disease convulsions and spasmodic muscular contractions, which are not especially characteristic of infantile and spinal paralysis. Another character of this febrile condition is its limited duration. West has recorded two cases in which the fever did not extend beyond one night; on the following day, paralysis set in in both instances. Whatever be its duration, the fever is almost always continuous, and if protracted, is more liable to assume the remittent than the intermittent type.

Let us now turn to the second, or paralytic stage of the disease.

We must remark, in the first place, that muscular power alone is impaired by the paralysis, which affects neither the intellect nor general or special sensation. Another noteworthy fact is, that from the onset the paralysis at once attains its highest amount in extent and intensity. The upper and lower extremities, the trunk and neck, are at once and simultaneously invaded. The child is utterly deprived of all power of motion. His legs bend beneath him, he cannot even sit up; and the paralysed muscles do not respond to electrical stimuli. In some few cases the paralysis may have a limited starting-point, but it must be remembered that, as a rule, the general character of the paralysis is pathognomonic of the affection. Habitually, however, the hands and arms are less severely afflicted than the legs and feet, and paraplegia is the form most commonly observed even at the beginning of the second stage; but, as we have remarked above, even when the loss of power is well marked in the upper extremities, it soon yields in accordance with the rule which governs the progress of the paralysis, and gradually disappears from the arms and becomes more and more circumscribed, until it settles finally in one limited set of muscles.

It is difficult to state with precision when the remission and localisation of the paralytic symptoms may be expected. Observation teaches that paraplegia is a first and temporary halting-place, and that after a time the paraplegic loss of power gradually becomes more limited. One limb at last recovers its action, and only certain sets of muscles of the other remain perfectly powerless, and become atrophied. The extensor communis, peronœi, tibialis anticus, and gastrocnæmei, being those most habitually engaged. The muscles of the thighs or arms are seldom similarly affected.

The secondary atrophy which marks the third stage of the disease is proportionate to the number of muscles involved, and the time the complaint has lasted. It sometimes makes its appearance very soon, but in general sets in only after an interval of several months, or even years. The limb shrinks to two-thirds or one-half of its natural size, and the skin assumes a dull, livid, withered aspect, as if the blood-vessels had, like the muscles, suffered a diminution in size: the thermometer further indicates that the temperature of the part is perceptibly lowered. Thus, when placed in contact with the skin, instead of marking 92 deg. or thereabouts, the thermometer falls to 68 deg. or even lower. The ligaments and bones participate in the general atrophy, and the process of the latter are less clearly defined. A shortening of the lower extremity of an inch or fifteen lines is generally observable, and the contraction may reach two, three, or three and a half inches, and thus induce a considerable amount of lameness. The wasted limb affords no support to the body, and the paralysis aggravated by the presence of atrophy, precludes walking exercise. The consistency of the part is soft and analogous to that of fatty growths. In addition, the loss of power in certain sets of muscles allows full play to the action of the antagonistic organs of motion, and induces the formation of the different varieties of club-foot, pes equinus, valgus, and more generally, varus, deformities which can be remedied but by the tenotomist.

When death supervenes from another cause during the progress of infantile spinal paralysis, the muscular fibre is found in a discoloured and attenuated state. On examination with the microscope, appearances vary according to the stage of the disorganisation; the transverse markings first cease to be perceptible in the ultimate fibres, and, subsequently, the longitudinal striæ; at a later date, the muscular fibrillæ are replaced by granulations, which are transmuted into fatty matter in the most advanced, and according to M. Duchenne, the final period of atrophy.

These changes in the muscular textures are, however, themselves but secondary, and the consequence of primary disease of the central parts of the nervous system, which

to be sought for in the portions which govern motility -viz., in the anterior columns of the cord. In one instance, which paralysis had existed for two years, the final fatty metamorphosis not being yet fully accomplished, the anterior columns were translucid and of a light roseate grey ue. On microscopic inspection, the nerve-fibres of the lumns were found distinctly reduced in size and number. he attenuated state of this segment of the cord formed a riking contrast with the perfect integrity of the posterior lumns, and afforded a satisfactory explanation of the full eservation of common sensation during life.

The description we have entered into of the symptoms iders it unnecessary to dwell on the diagnosis of the dise. No confusion is likely to arise with traumatic or aumatic paralysis, or the loss of muscular power consent on continued fever, or the painful contraction of the ubs, &c. The practitioner will especially bear in mind insidious beginnings of the affection, and the feverishs which precedes at a short interval the paralysis at t general, and promptly exhibiting a tendency to alisation. The paralysis may possibly escape notice at t, but, when observed, is pathognomonic. Spinal menin- is will be discriminated from infantile spinal paralysis by presence of impaired common sensation; in meningeal morrhage of the spine, the paralysis is attended with anic convulsions. In children, paraplegia is seldom the ult of any other disease than that under consideration. mary inflammation of the spinal cord entails loss of sen- on, as well as loss of motility, and the sphincters of the um and bladder participate in the muscular relaxation; paralysis has, moreover, more tendency to increase than liminish.

he causes of infantile spinal paralysis are obscure. In ost every instance, the feverishness sets in without any gible cause. The affection has been ascribed to exposure old, but paralysis due to this circumstance has another ct, and runs a different course. Amongst the internal es to which the disease may more legitimately be re- d, M. Roger notes childhood, especially early infancy. hirty-seven out of fifty-six cases, the age of the patients ed from six months to two years, seventeen were older ects, and in two or three instances only the children but a few weeks old. Fliess, Kennedy and West con- the disease with the process of teething, but M. Roger rks that teething and exposure to cold are daily oc- nces, and that the paralysis imputed to them is com- ively rare. They should, therefore, be viewed as mere idences; and, in short, we are compelled to acknow- that the true cause of spinal paralysis baffles our in- gation.

e disease, although not fatal in itself, is nevertheless mely formidable on account of the loss of muscular r it induces, and of the deformities consequent on hy. The question of treatment therefore deserves our ttention.

general medical assistance is called in too late to admit e application of the precept "*principiis obsta.*" If, ver, the practitioner is summoned in time, and is of the nature of the case, he should not hesitate to vour to allay the congestive irritation of the spinal by antiphlogistic treatment, proportionate in energy e age and strength of the patient. Leeches applied the spine, mercurial inunctions, and aperients, might ly exercise a beneficial influence. Calomel has in ases been extolled as the most efficacious of all anti- istic remedies, but it is obviously useful only in tran- paralysis, coinciding with gastric disturbance. In paralysis M. Roger prescribes calomel merely as an nt, if costiveness exists. It, is, however, but seldom nedical advice is called in in time to admit of any ac- eatment of the first stage of the disease; the practi- 's duty is usually confined to the management of the tic condition, which he should endeavour to relieve, r to obviate the occurrence of atrophy and its sequelæ, ter to remedy the deformities to which the affection ave given rise.

order to subdue the morbid action and restore the impaired muscular power, West recommends the local steam douche; in France, tepid-water douches have occasionally been found useful. Stimulating liniments, ammonia, Fioraventi's balsam (storax), linimentum terebinthinæ, a compound of one part of phosphorus and thirty of lard, &c., are also beneficial, and frictions with coarse wine are also a cheap and efficient remedy. Small blisters applied in succession along the sides of the spine, especially in the dorsal and lumbar regions, are also extremely serviceable. Very superficial cauterisation with an iron rod may also be resorted to for the purpose of counter-irritation, and leaves no scars. M. Roger also enumerated amongst the various means of treatment, saline, sulphurous, or sand-baths, or baths of wine-lees. If the patient's friends are in easy circumstances, Saint-Amand, Kreuznach, Bagnères-de-Luchon, Aix, are thermal stations which may be recommended, and also sea-bathing on the southern shores of France. All kinds of baths acting, however, on the entire surface of the integument, they should be prescribed on alternate days only, and in the intervals douches or rather local remedies must be applied to those regions which it is desirable more especially to stimulate.

In this respect, the method of treatment which seems at first sight most applicable is electrisation, the influence of which may be exclusively confined to the diseased organs, without interference with any others. M. Roger, therefore, recommends an early recourse to Faradisation, not as is usually practised after two or three months, but ten or fifteen days after the first appearance of the disease, and concomitantly with other therapeutic agents. Every other day ten or fifteen shocks, each lasting one second, should be imparted to the paralysed muscles, the entire operation lasting from five to ten minutes. Electricity thus applied, restores heat to the limb and equalises the temperature in both sides of the body. This system is eminently serviceable, and greatly assists the process of nutrition, and the return of the functional activity of the muscles, which are yet but weakened, and have not undergone the adipose metamorphosis.

This remedy is a painful one, it is true, but with proper precautions may easily be rendered bearable. In addition, the inductive apparatuses, which alone should be used in such cases, such as those adopted by Messrs. Duchenne, Gaiffe, Legendre, Morin, and others, determine powerful contractions of the muscular fibre, and give but little pain, and the good effects of the method fully counterbalance its disadvantages.

Should it, however, prove otherwise, and should it be impossible to bribe the little patients into compliance, other means must be resorted to. Gymnastics, although less efficacious than electricity, are yet a useful resource. Active exercises are, however, out of the question, unless the child is supported with proper appliances, leading strings, go-carts, or carriages moved by the automatic motion of pedals, &c. But passive gymnastics, imparted movements, shampooing and percussion of the muscles, the beneficial influence of which has perhaps been exaggerated by German and Swedish authors, should be employed with a view to the stimulation and restoration of the weakened muscles, and also to the removal of the tendency to deviation of the joints.

This remark forms a natural transition to orthopædic measures, especially in a prophylactic sense. It is highly desirable, in M. Roger's opinion, to lose no time in contending with the paralysis, and it is likewise necessary to use every effort to prevent deformities, which, once formed, may not be susceptible of cure. Without any delay, therefore, mechanical boots and appliances calculated to remedy club-foot should at once be resorted to. The shape of the boot and the support of the lateral rod keep the foot in the proper direction. It should be worn at night only, because its permanent use may prove too fatiguing, and because it is chiefly during sleep that the limbs, withdrawn from the influence of volition, assume the improper attitudes, prompted by the absence of equilibrium between the healthy and paralysed muscles.—'Journal of Practical Medicine and Surgery.'

THE MEDICAL CIRCULAR.

WEDNESDAY, SEPTEMBER 27, 1865.

ON THE DIFFERENCE BETWEEN LAW AND MEDICINE IN THE PUBLIC ESTIMATION.

In our last number there were two paragraphs of news, which, when viewed in juxta-position, exhibit, in a very forcible manner, the different modes in which Law and Medicine are regarded and appreciated by the public, and by those who administer justice in this country. One of the paragraphs was entitled "Unqualified Practitioners (of Law) in Police Courts," and it showed that in consequence of some alleged malpractices, the Lord Mayor had issued his dictum that for the future none but barristers, certificated attorneys, or their articled clerks should be allowed to conduct either a prosecution or a defence in his court. "*This salutary rule*," writes the newspaper from which the paragraph is extracted, "will prevent certain qualified practitioners from taking fees, and then leaving the business to be done by unqualified persons, *frequently to the detriment of prosecutors as well as prisoners.*" The paragraph goes on to state that a case occurred in which the Lord Mayor's "salutary rule" came into operation, for a person rose to defend a prisoner, and on being questioned, he said he had been thirty years in the Profession, but he had not taken out his certificate this year, and the Lord Mayor thereupon peremptorily declined to hear him.

Now, we admit that this rule of the Lord Mayor's is a very "salutary" one for the protection of the legal profession, because it forbids any persons, however able they may be, from exercising the functions of lawyers, unless they have been regularly admitted into the profession, and have paid the fees demanded for their certificates. But really we cannot see that any great "detriment" can follow to prosecutors or prisoners by the practice of such unqualified persons, in a country where the principles of free trade are so firmly established as in Great Britain, and where, we are told, everyone has a right to employ whomsoever he pleases to conduct his business. It really does not appear to us that it requires any extraordinary learning to enable a man to browbeat and abuse a witness, or to procure the conviction of a thief, or to rescue a prisoner from an unfounded charge. But the law says that none but lawyers shall perform these duties, and the Lord Mayor peremptorily refuses to hear a person (perhaps a very respectable and able man) upon the sole ground that he has not taken out a certificate to practise for the present year. We find no fault with the Lord Mayor's "salutary rule;" but, as we asked last week, why are not unqualified practitioners of Medicine treated in an equally summary manner? Is it supposed that the diagnosis and treatment of bronchitis or hydrocephalus are perfectly easy matters, while the question whether a man has or has not picked a pocket is a very difficult one, or is it absolutely necessary that a lawyer must be a man of education and a gentleman, while any illiterate scoundrel may practise Medicine with impunity?

But we now turn to the other paragraph to which we referred, and which is headed "Unqualified Medical Practitioners," and we shall see how differently custom deals in respect to Medicine. In this case there was a protracted inquiry before the Coroner for East Middlesex respecting the death of a child aged eight months, who was attended during its illness by a person, who though not duly qualified to practise Medicine, was in the habit of visiting patients. This person saw the deceased, prescribed medicines, and after the death of the child, gave a certificate as to the cause of death, which was duly received by the registrar of the district. The professional status of the unqualified practitioner may perhaps be best learned from his own words; and he tells us that "he has been practising as a surgeon for sixteen years. He had been a Medical student, but *he had not taken up his diploma, nor was he registered according to the Medical Act of Parliament.* The certificate of death was in his handwriting, and he kept a book with printed forms, which he obtained from the registrar of the district. He was in the habit of attending patients, *and he was of opinion that he had a right to do so.*" We may state at once that there was no evidence to show that this person caused the death of the deceased child, but the question was and is, whether he had any right to attend the child at all in a Medical capacity. The coroner informed him that he was liable to a prosecution under the Apothecaries' Act, and to a fine of 20*l.*, and one of the jury thought that he ought to be censured for acting as a surgeon without a diploma, but the other members of the jury objected to such a course, and ultimately brought in a verdict of "Natural death."

Now, either this unqualified Medical practitioner was treated very leniently, or the unqualified legal practitioner, who was summarily prevented from pleading before the Lord Mayor, was treated very harshly. The newspapers, too, which think the rule a very "salutary" one, which prevents an unqualified lawyer from defending a person who perhaps has picked a pocket, have nothing at all to say against a man who steps as it were between life and death, and professes to treat diseases without possessing any legal qualification to entitle him to do so. According to the old and rather vulgar adage, "what is sauce for a goose, is sauce for a gander;" and if an unqualified man is to be prevented from practising law, so ought an unqualified man to be prevented from practising Medicine.

As a subordinate incident in the case of the inquest, we find that the unqualified practitioner was in the habit of filling up certificates of death, the book with the printed forms being furnished to him by the registrar of the district. Surely the Registrar-General's attention ought to be drawn to the circumstance with the view of preventing such practices for the future.

Another instance of the relative powers and immunities possessed by Law and Medicine may be drawn from the case of the unfortunate Mr. Charles Gordon Sprague, who,

it will be recollected, was tried and acquitted on the charge of murdering some of his relatives by poison, and immediately afterwards was charged with committing a rape; and although the evidence on the latter accusation was of the weakest possible character, he was incarcerated in Newgate for upwards of a month, the Dogberry before whom he was charged, having refused to accept bail for his re-appearance. Dogberry probably thought that as the poor man was acquitted of the murder, he must be guilty of the rape; for upon no other mode of reasoning can we understand Mr. Sprague's committal to prison on the latter charge, which was wholly unsupported by a tittle of evidence, except that of the prosecutrix herself, from whose own statements and from whose own conduct the capital charge could not be sustained. Here was a gentleman (perhaps an imprudent one), locked up in Newgate on an accusation which was at once pronounced to be groundless, by the Grand Jury, before they had heard any defence, and who was at once liberated solely upon the evidence for the prosecution.

But it will perhaps be thought that Mr. Sprague has some redress against Dogberry, and that a British jury will give substantial damages to a man who has been locked up for a month, on a groundless charge, in a dismal cell in Newgate, and made to associate with murderers, thieves, and blackguards of all descriptions. Not at all. This gross iniquity has been committed under the sanction of the law, and Dogberrry may continue to eat his turtle-soup in security; but if a Medical practitioner had only expressed an opinion that some mischievous but cunning lunatic, or some patient with delirium tremens, ought to be restrained from injuring himself or others, he might become liable to be amerced in heavy damages, and even if he were victorious in the action, would have enormous costs to discharge.

Such are some of the contrasts exhibited between the modes in which Law and Medicine are respectively estimated by the community, and instances of the same kind are occurring every day. The Medical journalist has to refer to them only too often, but he may entertain a faint hope that some day the respective positions of Law and Medicine will be more equitably adjusted.

LONDON VESTRIES AND THEIR SANITARY WORK.

Under this title a pamphlet has just appeared from the pen of Mr. Rendle, late Medical Officer of Health for the parish of St. George's Southwark, and now a vestryman of that parish. The pamphlet is, in fact, a speech delivered by Mr. Rendle at a meeting of the vestry on the 8th of August last, and the questions he proposes for solution are whether London vestries are willing and able to do their sanitary work, and whether they may be trusted in the face of a severe epidemic? To both of these questions Mr. Rendle answers in the negative, and in the course of his very able and argumentative speech, he gives some good grounds for his opinion. He has formerly held the appointment of Medical Officer of Health, and is therefore able to speak from experience of the innumerable obstacles opposed to a gentleman who conscientiously desires to perform his duty, and he very plainly tells the vestry, of which he is now a member, of their shortcomings in reference to sanitary matters. It is not often that so much truth is told in a small compass as is contained in Mr. Rendle's speech, which deserves the careful perusal of all who desire to know something of parochial mismanagement. In the case of St. George's Southwark, it is perfectly monstrous to read of the enormous number of fever cases which have occurred in that parish, and which are distinctly traceable to the shameful neglect of sanitary precautions. We are horrified to learn that in less than five months of the year 1864, *one hundred and eighty-three cases* of fever were sent to the Fever Hospital from St. George's parish, and still more are we horrified at being told, on the authority of the Medical Officer of the London Fever Hospital, that these cases came continually, month by month, from the same buildings, or even the same building. The same authority tells us that houses from which five, six, seven, or eight typhus cases had been sent away, still remained utterly unregarded by the sanitary authorities, and were allowed to remain overcrowded and filthy in the extreme. Families, too, which had been frightened from their homes in consequence of having lost their relatives from fever in them, had had their places quickly supplied by fresh candidates for typhus, who entered infected rooms without even the form of cleansing having been gone through. Well may Mr. Rendle hold up such conduct as disgraceful to a Christian country, and well may he remark on the inconsistency of subscribing thousands to convert the Heathen in distant lands, when we permit such abominations to continue at home. We heartily agree with him in the following sentiments, which will be echoed by every right-minded person in the Empire. "If," says he, "we cannot mend this and similar evils, let us pray for different men and a different mode of election; let us have a municipality of parishes; or, as soon as possible, some central and powerful court of appeal; anything rather than the vile compromise at present in the ascendant." We also hope that he will persevere in the determination he expresses to petition the House of Commons for an inquiry leading to renovation and amendment. Although Mr. Rendle's observations are chiefly drawn from the parish with which he is immediately connected, they are, we fear, almost equally applicable to other parishes, and we hope that other sanitary reformers as vigorous as Mr. Rendle, will spring up elsewhere, to expose the shameful manner in which many local vestries neglect their duties, and trifle with the lives and health of the community.

THE CATTLE PLAGUE.

We regret to find that the disease among the horned cattle still continues its ravages, and fresh outbreaks are reported almost every day. It is a reproach to science that no definite opinions have yet been formed among

physicians and pathologists as to the nature of the disease itself, its mode of propagation, or the best means to adopt for its prevention or cure. With regard to the question of its being imported from abroad, we are not yet convinced that such has been the case, although the importation theory has been boldly advanced and maintained in various quarters, nor are we even persuaded that the disease is contagious in the strict sense of the term. We are pretty well convinced, on good authority, that the disease is *not* typhoid fever, at least if ulceration of the glands of the small intestine constitutes one of the main features of that complaint. We are by no means certain that the disease is incurable, and in fact, many cows sent to the slaughter-houses have been in process of recovery before they were killed; and many have been killed which were not suffering from the disease. That the malady, like influenza among the human race, is epidemic, there can be no doubt; but if, as we strongly believe, it is analogous to human influenza, the wholesale destruction of the animals is very much to be deplored, because many of them might recover under appropriate treatment, or under no treatment at all except temporary segregation. We hope that the Government and the public will not be led away by specious theories, but will regard the whole matter in a practical point of view; and will endeavour to stay the waste of animal life which is now being sanctioned by authority, to the great injury and privation of the inhabitants of this country without, as we believe, effecting any good results to the bovine race.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. HYDE SALTER continues his course of lectures "On Dyspnœa," and he now describes his mode of classifying dyspnœas in relation to their causes. There are three directions in which respiration may be injuriously affected—namely, on the side of blood-supply, or of air-supply, or through the nervous system; and as arranged under these three heads there appear to be six modes in which the conditions of normal respiration may be disturbed. These modes of dyspnœa may be caused—1. By the lung having more work to do than it is able to accomplish. 2. By the difficulty of getting air through the air-passages. 3. By the derangement of the forces of elasticity and muscular contractility. 4. By pain, as that of pleurodynia. 5. By direct obstruction of blood-vessels; and 6. The dyspnœa may be only nervous.——Dr. FRANCIS EDMUND ANSTIE contributes a paper "On the Physiological and Therapeutical Action of Alcohol." The paper is a controversial one, and is an answer to an article in another Journal (we believe the 'British Medical'), on the subject "Is Alcohol Food?" Dr. Anstie maintains that the sentiments expressed in the article in question are altogether erroneous, and that it is by no means proved, as asserted by the writer of the article, that the theory of MM. Lallemand, Duroy, and Perrin, is generally received, or that the views of Dr. Todd are devoid of a scientific basis. After arguing that the experiments of the French physiologists are open to great doubts as to their accuracy and conclusiveness, Dr. Anstie proceeds to vindicate Dr. Todd's theory and practice against the attacks which have lately been directed against them, and he deprecates the efforts which have been made to frighten the Profession from persisting in the inquiry as to the therapeutical properties of alcohol. In reference to the charge sometimes made against Medical men that they encourage drinking habits by the therapeutical administration of alcohol, Dr. Anstie remarks:—

"A word or two, in conclusion, about the insinuated charge against the alcoholic treatment of febrile states, that it lays the foundation of drinking habits. No man could sincerely make this statement who had studied alcoholismus chronicus on the large scale, and who, at the same time, was acquainted with the history of the growth of our knowledge of this subject. The clinical features of alcoholismus were very imperfectly known till the works of Roesch, of Magnus Huss, and (in this country) of Dr. Marcet, threw light upon the subject. We now diagnose with confidence the existence of concealed drinking habits in thousands of cases which would have passed undetected not many years since. One of the most remarkable features of these secret drinkers is their inordinate propensity to tell lies, and their favourite falsehood, when they are detected, is to lay the blame of their evil habit on some apocryphal Medical prescription of stimulants. Those observers, however, who have carefully studied the genesis of alcoholic excess are aware that the habit springs, in the immense majority of cases, from the temptation supplied by states of bodily or mental dejection and misery, and very often from a peculiar weakness of the nervous system which is *inherited*. These are facts of which the writer in the journal referred to appears to be ignorant, but which it was his bounden duty to have studied before he ventured to prefer a charge so deeply wounding to the reputation and the honour of the Medical Profession as that which he has rashly uttered."

Dr. GEORGE BUCHANAN, of Glasgow, continues his record of Clinical Surgical Cases, his present paper being "On Ligature of Arteries for Secondary Hæmorrhage," and he illustrates his remarks by details of operations on the common carotid, the posterior tibial, and the brachial arteries.——Dr. WILLIAM BAKER contributes a paper "On Ascites and its Treatment," illustrated by some brief remarks on three cases, which were treated by hydragogue purgatives and tapping.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. LIONEL BEALE continues his "Inquiry into the Nature of the Phenomena which constitute Inflammation," his present subject being Contagion. Dr. Beale believes that the efficient agents in contagion are minute bodies which are given off by infected organisms and enter into the tissues of animals. The mode by which their entrance is effected is thus explained:—

"How, then, do the living particles pass through the vascular walls and enter the blood, and what are the circumstances that would favour or interfere with their passage? Thin-walled capillary vessels, as is well known, come very near to the surface in many parts of the body. Those of parts of the mucous membrane of the nose, mouth, and conjunctivæ, even in a state of perfect health, are covered with a very thin layer of protective epithelium, while those of the air-cells of the lung are practically bare. In many morbid states the epithelial covering of the mucous membranes enumerated above is very soft, and sometimes it is reduced to a thin layer of a soft pulpy mucus, in which any foreign particles would very readily become embedded. It is reasonable to suppose that the contagious germs find in this soft mucus a nidus favourable for their reception, and at the same time soluble materials adapted for their nutrition. They would grow and mul-

tiply, and probably minute offsets from them would soon find their way to the external surface of the capillary walls."

These views, although hypothetical, are quite in accordance with the teaching of sanitary science, and the measures adopted by practical men for preventing contagion consist in the adoption of all such measures as are calculated to arrest the diffusion of the poisonous materials, or, as in the case of inoculation, to guard against a severe disease by communicating a mild one. Dr. Beale thus sums up his conclusions in reference to contagious diseases:—

"The *materies morbi* of contagious diseases does not consist of lifeless organic or inorganic matter, nor of any form of gas or vapour generated in the decomposition of animal or vegetable substances, nor of any matter set free during the decomposition of fæcal or excrementitious matter of animal origin; nor is it any species of animal or vegetable organism or parasite; but the active contagious material consists of exceedingly minute particles of living germinal matter which may be regarded as the direct descendants of the germinal or living matter of an organism which has been for some time living under unusual conditions. Contagious poisons affecting men and animals have originated in their organisms. The living or germinal matter of some contagious diseases originating in the bodies of animals may grow and multiply in man, and *vice versâ*. These particles of living germinal matter may retain their vitality for some time after they have escaped from the seat of their formation. They may pass through the air or be preserved in clothes, or various fluids, or moist solids. The smallest particle (less than the $\frac{1}{1000000}$th of an inch in diameter) being introduced into the body already in a fit state for its nutrition, may grow and multiply, giving rise, in due time, to the symptoms characteristic of the particular disease, and producing myriads of particles like itself. But it is probable that such particles, being introduced into a perfectly sound organism in a state of perfect health would not grow and multiply, but would die; or, in other words, such an organism would resist the influence of the contagious matter. Some of the germinal matter forming the *materies morbi* of certain contagious diseases may retain its vitality for a considerable period of time in a comparatively dry state, like vaccine lymph. Knowing what we do of the protective influence exerted by vaccination, it seems probable that the ravages of many other contagious diseases besides small-pox may be mitigated or prevented by the inoculation of certain forms of contagious matter which would produce allied but much less severe forms of disease. It seems desirable that numerous experiments should be instituted on cattle with the object of ascertaining if any such protective influence would be really exerted."

Mr. T. M. HARDING, in a paper "On the Alleged Degeneracy of Vaccine Lymph," treats of the subject of the degeneracy of vaccine lymph by frequent transmission. His opinion is that vaccination is not now so efficient as it was in the time of Jenner, and he recommends a recurrence to the original plan of taking the matter direct from the cow, in order to institute a fresh series of experiments on vaccination.

"CYCLOPS'" TWENTIETH LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—Dr. Lane, in the MEDICAL CIRCULAR of the 13th inst., says I did not explain the tetanic symptoms of his cases of cholera recorded in the MEDICAL CIRCULAR of the 23rd August. I thought I had done so. I wish, however, now to correct a few errors he has fallen into. It seems I called his cases "*erratic cholera*"—that is, a bastard sort of this disease, and not the true type; and afterwards styling them "*a disease simulating cholera.*" He says:—"Why say it resembles, when first he said *it was cholera?*" He will see that I said no such thing—*erratic* and *simulating* being two words expressive of the same meaning. Then speaking of the shock to the solar plexus, I said, "it is from this centre of the nerves that spasmodic cramps arise in true Asiatic cholera." Dr. Lane makes me say in the next line but one, that these spasms *only* arise in true Asiatic cholera. His own correct quotation of my observation proves that I did not use the word *only* at all; for this reason,—cramps like these may arise after an aggravated diarrhœa; or after much flooding in labours; or from loss of blood in mænorrhagia; or from a severe mental shock, &c., &c.; proving that I know they are not confined to Asiatic cholera, and that I could not mean for a moment they *only* happened in this disease; but being more severe and more marked in Asiatic cholera, I drew attention to the fact. His other observations on this point, he will see, necessarily fall to the ground.

Again, "to use the term extreme hyperæmia of the spinal and lymphatic nervous centres, is as difficult to understand as to apply;" whether the word lymphatic or sympathetic was used, makes no difference to the observation I made. I still maintain the opinion expressed in that sentence.

Now, the meaning of the term hyperæmia is understood differently by different persons. I think it was Andràl who used it, to imply a congestion of blood in a part, from whatever cause. Therefore, a clot of blood on the brain—an engorged state of blood in any collection of arteries—a congestion of blood in any set of veins, such as hæmorrhoids—an infiltration of blood in the capillaries, such as blood-shot eyes, or conjunctivitis—all would imply, according to Andràl's meaning, hyperæmia. Whereas, it is applied by others to denote any extra sensitiveness of the skin, or any other part. Therefore, until our Medical nomenclature is more defined, it is not possible to understand it. But supposing it to be present, one of two circumstances must happen. If Andràl's definition is correct, what does a hyperæmia produce on the part? Would it be obstructive to the electric action of the nerves, or would it excite their electric currents? A clot of blood on the brain, or a hyperæmia there, is evidently obstructive to the due performance of its functions. If, on "the spinal and sympathetic nervous centres," whereby I suppose is meant either semilunar, plexus, or both—namely, the solar plexus, does the same fact occur as if on the brain? I am inclined to take this view. If so, we can account for tetanic actions—namely, from arrest of electric currents which produces them; showing that the telegraphic wires or nerves are affected according to the pressure exercised upon them, and the correct or incorrect state of the batteries that influence them. But, on the other hand, if hyperæmia in any part produces excessive sensitiveness, then electric actions are inordinately excited, and pains are necessarily great and continuous. Then, again, some physiologists say that anæmia is the cause of pain along the nerves; while others attribute it to hyperæmia; so that, taking all these things together, any man who is in search of the truth, gets bewildered, not only with terms, but with dogmas. No wonder that physiology wants a closer attention paid to it, not only to sift the meaning of its terms, but to explain many of the actions of the body. Taking the meaning of "hyperæmia of the spinal and sympathetic nervous centres" as an explanation of "the tetanus," "the cord-like feeling across the chest," "the feeling as if cold water was running down the spine," and the fact of rice water stools being "cold as ice" when passed, would then imply, arrested electric currents in the "spinal and sympathetic nervous centres," which a consequent deficiency of caloric has produced. This reading of the fact I believe to be as correct as any other. But then, as I have said in one of my earliest letters, that the nerves are only wires, and that the batteries which make the electric aura, or certain combinations of elements which, in the performance of their duties, produce heat. We must conclude, then, that these batteries were stopped by a hyperæmia, and not only was all electric action stopped at

the same time, but heat also. Hence the "tetanus," "the cord-like feeling across the chest," "the feeling of cold water down the spine," and the rice water stools being "cold as ice." All produced by a temporary paralysis of nerve batteries. Can this hyperæmia be explained in any other way? As it stands by itself, it carries no explanation whatever. But, on the other hand, what was the cause of the hyperæmia? Was the course of the blood suddenly arrested in the "spinal and sympathetic nervous centres," or solar plexus? I should say nay to this, because the rapidity with which the cases recovered, rather forbids this view of the matter, and as Dr. Lane wishes these symptoms explained, and not the cholera, I thought I had done so by referring the cause to the destruction of electric-battery action in the solar plexus, the necessary result of which was many of the symptoms in his two cases of "*erratic*" or "*simulated* cholera." In giving my view of the treatment, I am sure Dr. Lane ought to be satisfied with my explanation of the action of his drugs and other remedies. I observed that, "to stop pain, arrest the fluxes, and restore the electric actions" are what true science is called upon to do, and which he says were "the very objects he had in view." I am glad of it, and hope these facts will be spread far and wide. I observed also that these cases of "*erratic*" or "*simulated cholera*" were frequent; whereat, he says (which God forbid), yet at the conclusion of his letter, he says he has had "*five more, but none so severe.*" Therefore, as he had seven, and I know many Medical friends who have had as many or more, none arriving at the dignity of true cholera, and I myself have had many cases during the last six weeks of the same *erratic character*, some of which have been congestive or acid; but as it so happens, the majority of mine have been inflammatory, and have been treated with the acids, anodynes, and opiates, instead of the alkalies, anodynes, and opiates, with very marked and good results. Dr. Lane is inclined to treat this great distinction lightly; but I may simply, in illustration of this, mention the difference between bronchial congestion and bronchitis. In the former, the bronchial tubes are loaded with mucus, the tongue furred, the pulse full, the skin moist and perspirable, with all the other characteristic conditions of a *congestive state*. The remedies are the alkalies and their carbonates, stimulating expectorants and good generous diet, plenty of fresh air, and everything done to promote the cough, in order to get the great mucus enemy out of the camp. On the other hand, bronchitis is an inflammation of the bronchial tubes. There is little or no mucus secretion on them; they are, in fact, bare of this secretion, not even having at times their proper diptherite covering; the tongue is dry and clean, or red in parts; the pulse sharp and wiry; the skin hot and dry, with other characteristics of the feverish state produced by inflammatory action. The cough is hard, because there is little or nothing to come up, caused by the mere irritation of air impinging on raw surfaces. The remedies are acids and opiates—the very opposites; in order to stop the coughing, which you dare not do with impunity in the other state, bland drinks, low diet, and as perfect freedom from the air as possible. These observations may be suggestive in cases of great diarrhœas, "simulating cholera." But Dr. Lane asks, "are the two forms of cholera to be discriminated by testing the *excreta*?" If he has no other means of diagnosis, he can do this, and may learn much by them. I have!

Dr. Lane asks me to enlighten my Medical brethren by giving the symptoms of each, as "if they are distinct types they must have different symptoms." Now, there a.e many symptoms in both these forms of cholera much alike; but it is only the careful observer of all facts that finds out and discriminates between the two. The same being necessary in other diseases; whether they be gout, rheumatism, or fever, &c. Disease is produced by a morbid or altered condition of the secretions generally, and must be cured through them; but as long as this fact is ignored, so long will disease of any character have its ever-varying forms of treatment, and which, to say the best of them, is only treating a NAME, and not a CAUSE. New ideas that would promote better principles are always somewhat sneered at. All new thoughts are very difficult even to be introduced and men forget, in the after usefulness of them, how much they were condemned at first.

In our own day, gas, steam, vaccination, and railroads, all had their clever and apparently worldly-wise scoffers. Where are they now?

Dr. Lane seems a little offended at my using the term "*empirically*." I did so because the practice of Medicine is yet but an *art and mystery*, NOT *a science*. If he were to have a run round the London hospitals this next season, he would see the same apparent disease not only treated differently in each, but differently by every physician. Not only this — he would hear the practice of Medicine differently taught at each hospital, and hear the most opposite opinions.

Now, most men believe they practice *scientifically*. The few who know most about the practice of Medicine shake their heads and regret they cannot. Each man prescribes to the best of his ability, but never with certainty. All may say, "Experiencia docet;" and as every man's experience guides him, and as all differ, then I use the term "empirically" for all. Dr. Lane's prescriptions were ordinary compositions (none the worse for that, by the way), and they did good. Twenty other men would, perhaps, have each given something different, according to their notions. Let him read in the Medical journals the different treatment of cholera, and he will see that I am right in what I say, and that every man thinks he is right in what he does. I wished to state the probable manner in which Dr. Lane's treatment accomplished a good result, in order that in some cases where the same treatment may be adopted and failed, that a watchful man like him would be induced to observe more closely the few hints I have thrown out and prescribe according to the morbid condition or state of the secretions, not for a mere name, because it is diarrhœa, "simulating cholera," or even a cholera itself. There is a physiological dogma much believed in, and that is, that in cholera, "a great deal of the watery part of the blood is eliminated and passed off by the vomiting and purging." I no not think this tenable. If we take the two distinct currents of the blood in health, and see how regularly they keep up a given standard, and are renewed by new ingesta through the lacteals, as well as by fresh elements from the body itself, through the lymphatics, we can then imagine that if a sudden stop takes place in all these phenomena, by a rapid evacuation of the contents of the whole alimentary canal, that many of the revivifying elements are at once lost to the blood. The heart's action still goes on; but every pulsation exhausts what blood there is in the body, and every hour the goodness of that stock is gradually reduced. For instance, what have the lacteals to take up? Nothing! for the whole alimentary canal is in an active state of endosmose, and whatever finds its way there, is immediately carried away. What have the lymphatics to do? Why, just as little; for if there are no elements sufficient for battery-power to the nerves, there are no superfluous ones for them to carry off. I do not, therefore, think it requires any emptying of the blood-vessels in the way physiologists have thus set forth. In fact, sudden death would occur if it were so; and if it is not, there would be very few recoveries. It is quite enough for them to bear the non-restoration of their elements without taking away from them what they have, which is hourly getting less, by the simple act of want of new supplies. This I believe to be a new idea on the subject, and opposed to current doctrines, which I am not bound to pin my faith upon, though I am equally bound, as a physiologist, to state what I believe more approximates to the truth. Therefore, I said the blood had nothing whatever to do with this disease, and I do not believe for a moment that cholera is produced by any morbid poison therein. The purple colour which the body assumes can be best accounted for on the principle I have laid down; for when the arterial supply is exhausted, and no new elements can be obtained, the venous blood must yet be exhausted before vitality ceases, and this being gradually done, what there left becomes ill-oxydised and ill-decarbonised in the last

from the absence of the natural heat of the body and other causes. For it does not follow that the blue or purple state is alone a sequence of cholera, as it is often seen in other diseases as well, and I could cite some extraordinary cases of this kind.

In the course of my papers, Dr. Lane and my other readers shall have the benefit of these.

I am, &c., CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

GENERAL CORRESPONDENCE.

INFANT BURIAL AND MEDICAL CERTIFICATES.

To the Editor of the Medical Circular.

SIR,—Not long since, a young woman applied at my surgery for advice for her baby, which was about twelve months old, but emaciated to the utmost degree, and evidently had been sadly neglected. I ascertained that it was illegitimate, and had been put out to nurse. The mother, however, evinced considerable anxiety for the child, and appeared, as far as her circumstances would admit, to tend it carefully. I saw it a few times, and then an interval of about a fortnight elapsed, when she called again, with her mother, to say that the child was dead, and to ask for a certificate. This I refused at the moment, and told her to call again; but I have never seen or heard of her from that time to this. I presume, therefore, that the child was buried, but how this was accomplished, and on whose authority, I know not. Perhaps some of your readers can inform me? Again, Sir, I see in the present number of the CIRCULAR that a Mr. Turner admits not having any qualification, and yet visits, prescribes, and gives certificates of death, as occasion requires, without let or hindrance; and though this is only one out of many cases, yet our Medical Council, or Licensing Bodies, our Government, don't interfere! Of what use, Sir, is it our registering at an expense of five guineas, under such miserable and unfair management? It can only be to support those in luxury who are fortunate enough to get appointed. Surely, sir, death certificate books should be supplied with as much care as cheque books, and kept as carefully under lock and key, otherwise, how easy is it for a man capable of a greater crime, to get one of these papers and forge a Medical man's name to secure the burial. Pray, Sir, bring a powerful leader to bear on these abuses, and urge the Profession to agitate their rights.

I am, &c.,
H.C.

GRIFFIN TESTIMONIAL FUND.

To the Editor of the Medical Circular.

SIR,—At the last meeting of the Committee, it was resolved that the above fund should be definitely closed. Intending subscribers will oblige by forwarding their contributions on or before October, 31st proximo.—I am, &c.,

145 Bishopsgate Without, ROBERT FOWLER, M.D.,
Sept. 6th, 1865. Treasurer and Hon Sec.

CASE OF ALLEGED POISONING BY STRYCHNIA AT SALISBURY.

On Wednesday the adjourned inquest on the body of Miss Emily Sophia Blake was resumed.—The deceased was daughter of Mr. T. J. Blake, surgeon, of Castle street, Salisbury, and was 19 years of age. It appeared from evidence taken previously that on the night of Tuesday, the 5 inst., Mr. and Mrs. Blake were alarmed by hearing cries from the bedroom of the deceased. They proceeded to the spot and found her in great agony and screaming loudly. Her body was rigid, and she exhibited all the symptoms of having been poisoned by strychnine. They sent for Dr. Roberts and Mr. W. M. Coates, who shortly afterwards arrived. She admitted to Dr. Roberts, when told she was dying, that she had taken three pills which had been given to her by Mr. William John Storer, who had been her father's assistant some time before. Dr. Roberts asked her if any of the pills were left, and she said there was a box of them in the dressing-table drawer, where the box was found. She then fell into convulsions, and died.

Dr. Alfred Swaine Taylor, M.D., F.R.S., said,—On Thursday, the 7th of September, 1863, I received,—first, a jar containing, as it was alleged, portions of the viscera of the deceased; secondly, a small bottle; and, thirdly, a box containing pills. The pills in the box were twelve in number. The average weight of each was rather more than four grains. They were of a brown colour, and had an aromatic smell. They were soft, as if made with treacle or syrup. Under the microscope they presented no unusual appearance. No crystalline or mineral matter could be perceived in them. They contained neither arsenic, antimony, nor mercury, but they contained a large proportion of sugar, with vegetable matter similar to the aromatic confection of the Pharmacopœia. Three of the pills weighing 12·6 grains were submitted to the usual processes for the detection of strychnia and other alkaloids of the like nature. Strychnia was separated from them in a crystalline state, and distinctly identified by all of its principal chymical properties. The decoction of the pills in water and spirit had the intensely bitter taste of strychnia. This taste remained upon the tongue for more than an hour. From the three pills a quantity of strychnia equivalent to half a grain was separated. Assuming that the strychnine was equally distributed among them this would make a proportion of one-sixth part of a grain for each pill. By another chymical process the strychnine contained in the half of another pill was extracted. This was found to be equivalent to one-tenth part of a grain, or representing one fifth part of a grain for each pill. By another chymical process the strychnia contained in the half of another pill was extracted. This was found to be equivalent to one-tenth part of a grain, or representing one-fifth part of a grain for each pill. Considering that it is exceedingly difficult to extract the whole of the strychnia contained in a pill under such circumstances, it may be inferred that each pill would not contain less than from one-sixth to one-fifth of a grain, and that three pills would therefore contain from three-fifths to one-half of a grain. Three other pills taken from the box were made into an extract with spirit (for dissolving the strychnia), and one-half of this extract was placed within a wound made in the skin of a rabbit. In four minutes the animal was seized with the usual tetanic convulsions which are produced by strychnia. These followed each other in rapid succession, and the animal died in three minutes, making altogether seven minutes from the time at which the extract, equivalent to one pill and a half, was placed beneath the skin. The bottle of blood contained seven drachms, or about a tablespoonful, of blood of a dark crimson colour, not putrid. It presented no unusual appearance under the microscope, and chymical analysis did not show in it the presence of any strychnia. The quantity here examined is equivalent to only 1-500th part of the blood contained in the body of an adult. The contents of the jar.—The jar contained—first, the stomach unopened, and the two ends properly secured by ligatures, so that none of the contents had escaped; secondly, the large and small intestines; thirdly, a portion of the liver; and fourthly, the spleen. These organs, it may be observed, were healthy, and presented no appearance which would account for death; they were remarkably free from putrefaction. As to the stomach, on the outside of this organ there was a deep patch of a red colour, corresponding to the situation of the spleen. When opened the stomach was found to contain about six ounces, by measure, of half digested food of a thick pasty consistency, and of a sour smell, as if it had undergone fermentation after death. No pills could be seen in the contents, but the following substances were recognised and separated:—The pips and skins as well as the pulp of apples, French beans, the fibre of meat, and a quantity of bread (starchy matter), as well as fat. These were partially digested, showing that death

must have taken place suddenly soon after a full meal had been made. There was no odour of prussic acid, spirits, or other poisonous volatile liquids. The contents were acid, probably as a result of the fermentation of the food. The inner surface of the stomach presented a few patches of congestion, and it was slightly reddened, but there was no appearance of disease to account for death. The whole of the contents, with the mucus scraped from the inner surface of the stomach, were submitted to the same chymical processes as the pills for the detection of strychnia. The result was that slight traces of that substance were detected in the liquid portion of the contents. The intestines presented nothing unusual, either internally or externally. They were in some places reddened, apparently as the result of congestion; but on opening them they contained the usual healthy substances derived from digested food, and the lining membrane presented no appearance of disease. As to the liver and spleen, four ounces of the liver and the whole of the spleen were minutely examined for strychnia, but no trace of this poison was detected in either organ. The conclusions, which I draw from this analysis, are—First, that the pills contained strychnia in a quantity sufficient to cause death, according to the number taken; secondly, that there were traces of strychnia in the contents of the stomach; thirdly, that there was no strychnia in the liver, spleen, and blood. Assuming that three pills had been taken shortly before the death of the deceased, and that they contained a similar amount of strychnia to that which I examined, I should not have expected to find greater and more distinct traces of strychnia in the stomach of the deceased than I did. The dose was very small. I should state that the longer a person lives after taking poison, the less trace of it is found, as it becomes absorbed into the system. I should not have expected to find it in the blood. Had it all been there the proportion would only have been the fiftieth part of a grain to 1 lb. of blood. Assuming the quantity of strychnia to have been taken which I discovered in the three pills, I should not have expected to find any traces in the liver or spleen. Half a grain of strychnia would destroy the life of an adult. Strychnia is given in cases of paralysis and nervous affections; but the medicinal dose would commence at the twentieth part of a grain, and increase to a twelfth, or even a tenth part of a grain. I may add that symptoms of poisoning begin in doses from a quarter to a third of a grain, and actual death has taken place in two known instances from a quantity equivalent to that which is before you. The quantity of strychnia I found in the deceased is consistent with either a poisonous or a medicinal dose. From the traces found in the stomach I can draw no inference; the residue was consistent with either, as I have said, so that I can form no conclusion as to the cause of death. I cannot conceive that strychnia would be a proper medicine for the purpose of procuring abortion. I have never heard of it. I can conceive no other effect than convulsions resulting in death. The action of strychnia is over the voluntary muscles, and I have not heard of its action on the uterus. I do not think one pill would destroy life; two might have jeopardized it; but three would, I think, have been fatal to any one. It is possible that one pill may contain more than another; but from the analysis I made I take it that the strychnia in them was pretty equally divided, and that any adult taking three of those pills would die.

The Coroner directed the jury in his summing up that if the pills containing strychnia were given by an unqualified man through ignorance, and death resulted, they (the jury) should return a verdict of manslaughter; but if that medicine was administered with "malice," then it would be in the eye of the law murder.

The jury retired at half-past 5, and, after an absence of half an hour, returned the following verdict:—"We find that the deceased Emily Sophia Blake died from the effects of strychnia taken by her in three pills, given to her by William John Storer, and we find a verdict of manslaughter against the said William John Storer."

OBITUARY.

R. WOLLASTON, M.R.C.P.

Dr. Wollaston was a few years ago appointed one of the Physicians to the South Staffordshire Hospital, in this town, upon the resignation of Dr. Topham. He held that appointment for about two years. Subsequently he removed to Stafford, having been elected Physician to the Staffordshire Infirmary, and Visiting Physician to the Coton Hill Asylum. After discharging the duties of those offices for some time, the state of Mrs. Wollaston's health induced Dr. Wollaston to remove to a warmer climate, and he proceeded to Italy. For some time past he had been engaged in Rome studying antiquities, especially ancient mosaics, a subject with which he was well acquainted. He afterwards went to Naples with the intention of pursuing similar studies at Pompeii, but was prevented carrying out this object by an attack of illness, which terminated in his death. Exposure to the sun's heat in the streets of Naples brought on congestion of the brain, followed by diarrhœa and inflamation of the lungs. On the 16th ult., Dr. Topham, of Rome, who was staying at Sorrento, was telegraphed to go to Naples to visit Dr. Wollaston, in consequence of his illness having become serious. Dr. Topham visited Dr. Wollaston three times, staying the night on each occasion. Notwithstanding, however, all that Medical skill and human aid could afford, Dr. Wollaston expired on the 22nd ult. It is a somewhat remarkable circumstance that Dr. Topham, whose successor Dr. Wollaston was in the South Staffordshire Hospital, should have attended him at his death in Naples, and that the Rev. Pelham Maitland, formerly Vicar of St. James's, Wolverhampton, should have performed the funeral ceremony at his interment in the English burial-ground in that city, his friend Dr. Topham attending the funeral. We may add that Dr. Wollaston, who was well versed in antiquarian and archæological subjects, was a schoolfellow of the late Lord Macaulay. He was apprenticed to a leading hospital surgeon in London, and afterwards went to Clapham, where, through the kindness and influence of Dr. Darling, a physician practising in Russell square, London, he was introduced to a good local connexion. Amongst other patients in the higher ranks of life, he attended the late Sir J. Mackintosh. Having married, Dr. Wollaston removed to Westbourne terrace, London, where for many years he enjoyed a large and lucrative practice. His wife, however, suddenly died, and this event so completely unnerved him that he sold his practice, and an opportunity presenting itself, during the Crimean War, he accepted an appointment as Physician to the Hospital at Scutari. On the termination of the war he returned to England, and married the present Mrs. Wollaston, resuming practice at Cheltenham. He subsequently removed to Wolverhampton, having always had a strong desire to be connected with some public institution. Dr. Wollaston was, we believe, at the time of his death, upwards of sixty years of age. As an author, he was known by his "Memoir on the Turkish Bath," and by an elegant treatise on the "Baths of Ancient Rome." Dr. Wollaston was connected with the same family as his namesake, Dr. Wollaston—the celebrated author of "The Religion of Nature," who was a native of Staffordshire.—'Wolverhampton Chronicle.'

JOHN GLOVER LOY, M.D. EDIN.

This gentleman, who was in practice at Whitby sixty-four years, died there on the 4th inst., aged ninety. His talents were of a high order. Great and general was the esteem in which he was held during his long, active, and successful career.

His pamphlet, "Experiments on the Origin of Cow-Pox," published in 1801, attracted particular notice everywhere, at home and abroad, by those to whom the subject had become a matter of interest, and brought him into correspondence with some distinguished Medical and scientific men, including the late Dr. Carro, of Vienna, who published a German translation of it; Sacco, of Milan, Dr. Jenner himself, and others. From their first appearance

own to the present time, Dr. Loy and these (his experi-ents) have been commonly quoted by the various authors ho have treated of the subject of cow-pox. To show the markable power and retention of his faculties, mental d physical, up to so late a stage of life, may be recorded successful operation performed by him in May last—viz., e excision of a female's cancerous breast. Dr. Loy's rare ilities and just reputation entitle him to more than a ere passing notice.

URETHROTOMY.

We now advert to the discussion which recently took ce at the Society of Surgery, on the subject of internal throtomy. We stated that the members almost unani-usly agreed in the views brought forward by M. Perrin. e assertion was premature. The debate was apparently austed, when it was revived by criticisms adduced by A. Guérin. M. Dolbeau endeavoured to defend his ctice, and MM. Voillemier and Démarquay dealt paringly with the arguments of the exclusive partisans urethrotomy.

rom an attentive perusal of the observations which fell n the different speakers, and the reply of Dr. Perrin, conceive that the practical inferences from the debate be summarised as follows :—

s we stated before, incision from within is not appli-le in every case of stricture ; it is the surgeon's last ource, but as such sometimes yields unhoped-for results, may be instrumental in saving the patient's life. ed, when all attempts at dilatation by the various ods in use have failed, when the introduction of the slender bougies has been found utterly impracticable sufficient to check in time the symptoms consequent etention of urine, the practitioner is compelled either uncture the bladder, to open the urethra behind the ture in the manner described by Elliston, or to perform rotomy. Now, although puncture of the bladder is perfectly successful, an assertion fully borne out in a t case observed in M. Jarjavay's practice, we have esitation in acknowledging that we prefer incision of rethra, if the same object is attainable by this proce-

We agree, however, with M. Démarquay, that rotomy should be viewed merely as an auxiliary to ation, and should be resorted to under the following nstances only :—1. In the case of fibrous strictures ilatable beyond a certain point, especially if sinuses lso present. 2. For retractile strictures, which yield mporary manner to dilatation, but promptly relapse. irritable strictures. In many individuals, a bougie ertain size can be introduced with perfect ease, but ttempt to insert a sound of larger diameter induces sh symptoms of a more or less serious character. In cases, urethrotomy supplies the surgeon with the of removing all these morbid phenomena, and ates the introduction of voluminous catheters.

MEDICAL NEWS.

THECARIES' HALL.—The following gentleman passed amination in the Science and Practice of Medicine eceived a certificate to practise on the 31st ult :—

Fitzpatrick, Northampton.

LTH OF THE NAVY.—The Statistical Report of the t of the Navy for the year 1862 has just been issued, the superintendence of Dr. Mackay. The mortality s to be 9·1 per 1,000.

REY COUNTY HOSPITAL.—Her Majesty has graciously d her intention of presenting a bust of the late Consort, executed by Theed, to the Surrey County al, to be placed in the corridor of the building, which nearly ready for the reception of patients.

OME AND INSTITUTION FOR TRAINING NURSES, is o be formed in Southampton for Hampshire, on the lan as that which has been in operation for three uccessfully in Bath.

DEATH OF DR. FORREST, C.B.—Inspector-General of Hospitals, John Forrest, M.D., C.B., died at 10 Queen's parade, Bath, on the 10th inst , aged 61 years. Dr. Forrest, who was an Honorary Physician to the Queen, entered the army November 10, 1825, and served in the expedition against the Rajah of Kolapore, in 1827 ; he was also employed during the expedition against the insurgent Boers beyond the Orange river in 1845 ; and in the Kaffir war of 1846, for which he received a medal. He was in Medical charge of the 3rd division of the Eastern army at Gallipoli and Bulgaria, and accompanied the expedition to the Crimea in September, 1854, and was present at the affair at Bulgarnac, capture of Balaklava, battles of the Alma and Inkerman, and siege of Sebastopol, and was noticed in Lord Raglan's despatch after Inkerman "for his able exertions as deserving to be most honourably mentioned." He was rewarded with the medal with three clasps, made a C.B., and received the fourth-class order of the Medjidie. He became Inspector-General December 31, 1858, and was stationed at Malta until December, 1861.

THE HERBERT CONVALESCENT HOME.—On Saturday week, the foundation-stone of this institution was laid, at Bournemouth, in memory of the late Lord Herbert of Lea, by his youthful son, the Earl of Pembroke. The "Home" will be connected with the Salisbury Infirmary, in which the late Lord Herbert took a deep interest.

THE DANGER OF ACTING UPON CERTIFICATES OF LUNACY.—MARLBOROUGH STREET.—Henry Thomas Durrant, engineer, No 23 Little Drummond street, was brought up before Mr. Knox, charged with assaulting James Powell, an ex-constable of the C division. The complainant said he lived at No 6½ Oxford market. About half-past six o'clock on Wednesday evening, while lying down, his wife brought the prisoner and another man into the room. When the prisoner saw him he said, "We have got you now, and we mean to take you in a cab to the Marylebone Workhouse." The prisoner then struck him on the face and threw him back, while his wife and another man held him forcibly down and placed a pair of handcuffs on his wrists. His legs were then tied together, and while this was being done he called "Police !" and "Murder !" The outcry he made caused several persons in the house to come to his assistance, when he gave the prisoner into custody. It was not the first time his wife had acted in the same way. Mr. Stone, the landlord of the house, said he had always known the complainant to bear the character of a quiet, inoffensive man. Hearing a disturbance last night, he went upstairs and found the complainant lying on the bed with his legs tied together and handcuffs on his wrists. As it was not the first time the complainant's wife had brought men to the house, he detained the prisoner and gave him into custody. A police-constable said he found the complainant as described. The prisoner said he had lost the key of the handcuffs and could not unfasten them. The wife had been to him several times to take the complainant into custody on the plea that he was mad. The complainant's wife handed to the magistrate a certificate signed by Mr. Clapp, for the complainant to be admitted into the insane ward of Marylebone. Mr. Knox asked the complainant if Mr. Clapp had ever examined him. The complainant said he had never seen Mr. Clapp in his life. In reply to a question by Mr. Knox, the prisoner said that he had acted not under the authority of the parish, but under the authority of the complainant's wife. He was a ship engineer, and had just come home from a long voyage. Inspector Silverton said the wife of the complainant had told him at the station that her husband was mad. He had known the complainant for some years, but had never noticed anything like madness about him. Mr. Knox said the wife had also complained to him on the same subject. Shortly afterwards Mr. Tubbs, the overseer of Marylebone, and Mr. Clapp, who had been sent for, entered the court. Mr. Knox said he wanted an explanation of the certificate signed by Mr. Clapp. Mr. Tubbs said Mr. Clapp, issued an order for the admission of the complainant, but, when the order was brought to him, he declined to send an

officer to take the complainant. He told the complainant's wife if she apprehended danger, and would bring her husband to the house, he would take him in, and then after he had been seen by a magistrate he would be sent to Hanwell if expedient. The complainant was brought to the house, but he ran away, and no steps were taken to recapture him. He heard nothing more of the case until a certificate was brought to his office yesterday. The parish had nothing to do with what took place. Mr. Clapp.—I gave the certificate on the 7th inst. It was only put in force on Wednesday, and when I gave it the complainant was labouring under delirium tremens. The prisoner in defence said,—I met Mrs. Powell last night and she asked me to take her husband to the workhouse, as she could not get anyone to do the job. She told me she had the proper papers from the magistrate and the workhouse; that there would be no danger to me; that the neighbours would not interfere, as they knew what her husband was. I went to the house, and the complainant threw a boot at me. I helped to secure him, but I never struck him. Mr. Knox. —I do not think the prisoner has been actuated by malicious motives, and I shall, therefore, instead of sending the case for trial, as I intended, deal with it as one of assault and fine him 5*l.*, with the alternative of one month's imprisonment. I declare emphatically that but for the unfortunate circumstance of Mr. Clapp having issued a certificate to the wife the present case would never have occurred, but at the same time I must acquit Mr. Clapp of having been actuated by any improper motive in signing the certificate.

ARMY SURGEONS.—*Return to an Address of the Honourable the House of Commons, dated 22nd May,* 1865:—for, "Returns of number of Assistant-Surgeons at present in Her Majesty's Service, exclusive of the Indian Army; and, of number of Assistant-Surgeons promoted to the rank of Surgeon during the last three years, specifying the number in each year."—HARTINGTON, War Office, May 25, 1865.—— Return showing number of Assistant-Surgeons at present in Her Majesty's Service, exclusive of the Indian Army:— 738.—Return showing number of Assistant-Surgeons promoted to the rank of Surgeon during the last three years: —Year ending 31st March, 1863, 16; year ending 31st March, 1864, 19; year ending 31st March, 1865, 20.

PRESENTATION OF ADDRESS AND TESTIMONIAL OF 800 SOVEREIGNS TO JOHN HARRISON, ESQ., M.D. OF ROSCOMMON. —The following address with the accompanying testimonial was presented on the 2nd September by the Right Hon. Lord Crofton, Chairman of the Committee, on the part of the subscribers, and as inscribed on the lid of the casket:— "ADDRESS.—*Presented by* 305 *Ladies and Gentlemen to John Harrison, Esq., M.D.*—In grateful recognition of the consummate ability, the unostentatious liberality, and the universal devotion which have eminently distinguished his lengthened professional career, and which have insured for him the respect, and won for him the affection, of all ranks and classes of society.—CROFTON, Chairman of Committee." The amount subscribed was 816*l.*; and Dr. Harrison made the following reply:—"*My Lord and Gentlemen.*—If ever there was an occasion, when one must fail to express what he feels, surely the present is that occasion, and if I fail to say, as I must, what is in any measure suitable and due, I am sure, my Lord and Gentlemen, that you will at least give me credit for what I feel. The proudest day of a man's existence must necessarily be the day most replete with feeling, and this being the proudest and happiest day of mine, lays claim to feelings of the deepest gratitude and sincerity. (Applause.) But, my Lord and Gentlemen, you have over-rated my deserts, you have put too high a value upon what was but a duty; if I have been in any way instrumental in lessening sorrow for, and in increasing the happiness of, the home circle, it was my greatest ambition to do so, and my highest recompense that it was felt, whilst most of the success must be attributed to the courtesy and kindness and ready co-operation I invariably met at the hands of your Lordship and the other members of the public institutions to which I am attached, but the evidence of appreciation manifested here to-day is so much beyond what I either hoped or imagined, that I must ask to remain a debtor still to such noble generosity and such generous consideration; nor can I rest at this, there is another feature that, as it were, puts a crown upon the gift, and enhances it a hundred times, if enhanced it could be, and that is the spontaneous unsolicited promptitude with which the movement was carried to its great success by the rank and beauty of the county—initiated by no less a personage than Lady Crofton herself. To the ladies then, in a more especial manner, is my gratitude conveyed, and whilst I shall retain the liveliest recollection during life of all my friends, and all their kindness, the memory of the ladies, who were ever my fast and fondest friends, shall be cherished and esteemed in my latest remembrance.

HEALTH OF THE NAVY.—The Report just issued on the Health of the Navy in the year 1862, shows that the number daily sick was 3,370, or 57 per 1,000 of the force in the service afloat corrected for time, which was 58.870. There were almost exactly three entries on the sick-list for every two men, and a mean of about eighteen days' sickness to each man of the force. But a very large proportion indeed of the sick rate in the Royal navy is from boils, simple catarrh, and injuries of a more or less trivial nature, the duties of the man-of-war's man involving such constant exertion that it is necessary to pay much more attention to trifling ailments than their immediate importance would seem to call for, in order to avoid the risk of their aggravation. The ratio of sickness from diseases, properly so called, is in reality very small. The Cape station showed the highest rate in 1862, owing to duties in the Mozambique Channel and in the Zambesi river. The number of men invalided from the navy in the year was 1,944, or 33 per 1,000; and the number of deaths was 15·3 per 1,000. But eliminating disturbing elements arising from accidental duties, that is to say, excluding deaths from casualties by wounds and injuries and deaths from outbreaks of cholera and yellow fever, the death-rate in the service as a service is reduced to 9·6 per 1,000, which is very little higher than the death-rate among the healthiest class of outdoor labourers in England. It may be said the death-rate in the navy is reduced by invaliding, but the vast majority of invalided men labour under diseases by no means a fatal nature, and very many of them return the service. The rate of mortality on the Cape station was as high as 23·7 per 1,000; but the station had to sustain the loss of two boats' crews massacred at Bareia, in the Arabian Gulf, by Somalis, to whom they had applied for goats and water. Excluding deaths by violence, the rate of mortality at this station was only 4·3. On the East and China station the mortality rose to no less than 61 per 1,000, the great majority of deaths being from dysentery and cholera, contracted in river service against the Taepings. The surgeon of the Euryalus sketches incidentally a fearful picture of the state of Shanghai, to which his ship returned after the capture of Kahding. He says he learnt that the mortality among the Chinese who had crowded into Shanghai for refuge was at one time so great that there was no burial-ground for about 2,000 of the daily deaths, and the corpses were enclosed in boxes of boards, loosely put together, or packed up in straw matting, and left to rot in the sun. Then, again, the mortality on the American coast has to bear a certain number of deaths caused by the Mexican expedition. Vera Cruz is a city of open sewers, and is situated on a level surface, the fall towards the sea being so trifling that the courses of foul water, &c., require repeated sweeping during the day. The Mexicans are very particular as regards this matter of cleanliness, but under the conjoint rule of France, Spain and England, it became neglected, and the neglect is avenged. The accumulation of offal is kept down by the turkey buzzards, everything being placed on the outside of the houses for removal by these, the scavengers of the place. But besides perils abroad from foes to health and life, Dr. Mackay has the old tale to tell in this report of foes in our own household. On the very threshold of the seaman's entry into the service, and in the seaport towns of his own country, he has been left exposed to such a mass of diseases as renders these localities more destructive

lth than the most pestilential rivers of Africa. It is sidered that from Portsmouth and Plymouth more hilitic disease has been sown broadcast over the globe n from any other cities on the face of the earth. Partial sures have at length been devised to mitigate this evil, it is hoped the day is not far distant when effectual s shall be taken to remove to the utmost this foul dal from the nation. The surgeon of the Euryalus has on to believe that most of the forty-eight cases of hilis in his return for the first quarter of the year were ght in the same house at Portsmouth; therefore, he , "the sanitary precautions necessary for preventing a common source of immense loss of labour to the ice are simple enough." "I have now," he says, "a under treatment who has had successively the primary, ndary, and tertiary forms of the disease; a strong, young man when he joined the ship, he has now be- e useless to the service. It is one example among y." The disease was almost unknown in Malta until), owing to a system of surveillance established by om, but whether derived from the knights or from the ich it is not easy to say. In 1860, the Maltese women, overing that there was no law upon the subject, refused ibmit to the rules of custom. The results of this sus- ion of surveillance were unhappily so marked that it found necessary to pass an ordinance in 1861 reviving The beneficial consequences of this law, writes the uty Inspector-General, "have far exceeded my best ctations." Facts like these are unmistakable. The and antidote are both before us.

ANITARY WORKS.—Dr Buchanan is at present engaged aking an inspection of various towns in the kingdom, a commission from the Privy Council, with a view certain what have been the effects produced upon the lic health by works of drainage, water-supply, and sanitary measures. He has already visited several hern towns, and is at present engaged in conducting a lar inquiry at Carlisle, where much has been done in ay of sanitary reform during the past twenty years.

SPECTION OF EXAMINATIONS.—The Branch Medical ncil for Scotland some time ago organised a system of ation of examinations, in compliance with a resolu- passed by the General Medical Council in its last on. On August 15th the Irish Branch Council made intments for the same purpose, as follows: Dr. Stokes Dr. Aquilla Smith, to visit the examinations at the College of Surgeons; Dr. Hargrave and Dr. Apjohn, it the examinations at the King and Queen's College ysicians; Dr. Corrigan and Dr. Hargrave, to visit the inations at Trinity College; Dr. Leet and Dr. Stokes, sit the examinations at the Queen's University; Dr. and Dr. Apjohn, to visit the examinations at the hecaries' Hall. Dr. Corrigan having declined to act, eet was requested to act with Dr. Hargrave in inspect- ne examinations in Trinity College.

GOOD EXAMPLE.—The Exeter Town Council have ed their body into committees, with the view of ng a house-to-house visitation for the purpose of cting the drainage, and promoting the venlation andit sing of the dwellings in the various streets and lanes e city.

APPOINTMENTS FOR THE WEEK.

SDAY, SEPT. 27.—Operations at Middlesex Hospital, 1 p.m.; St. 's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Lern Hospital, 2 p.m.; University College Hospital, 2 p.m.; Lon- Hospital, 2 p.m.

DAY, SEPT. 28.—Operations at the Central London Ophthalmic ital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical e, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hos- 2 p.m.

, SEPT. 29.—Operations at the Westminster Ophthalmic Hospital, m.

AY, SEPT. 30.—Operations at St. Thomas's Hospital, 1 p.m.; St. olomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; l Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

Y, OCT. 2.—Operations at St. Mark's Hospital for Fistula and Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2

Y, OCT. 3.—Operations at Guy's Hospital, 1½ p.m.; Westminster tal, 2 p.m

BOOKS RECEIVED FOR REVIEW.

Winter in the South of Europe. By J. Henry Bennet, M.D. Third Edition. London: Churchill and Sons.

Contributions to Dermatology. No III., on Psoriasis and Lepra. By T. McCall Anderson, M.D., &c. London: John Churchill and Sons, New Burlington street.

A Practical Essay on the Use of the Nitrate of Silver in the Treatment of Inflammation, Wounds, and Ulcers. By John Higginbottom, F.R.S. Third Edition. London: John Churchill and Sons.

San Remo as a Winter Residence. By an Invalid. London: John Churchill and Sons.

Cholera: its Pathology, Diagnosis, and Treatment. By Wm. Story. London: E. and F. N. Spon, 16 Bucklersbury.

A Description of the Diseased Conditions of the Knee-Joint. By Peter C. Price. Edited, with a Preface and Memoir of the Author, by Henry Smith, F.R.C.S. London: John Churchill and Sons.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the OFFICE BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross post-office.

INQUIRER.—We think that our correspondent will obtain what is required at Messrs. Chandler, Berners street, Oxford street.

R. S.—The book has been received, and will be noticed in due course of time.

OMEGA.—It does not appear to us that the conduct of Dr. C. in the case alluded to, was in any respect deserving of blame.

A STUDENT.—The registration at the Branch Registrar's office does not supersede the necessity of registering at the different licensing bodies, although it may eventually have that effect.

MEDICAL DEGREES WITHOUT RESIDENCE.

TO THE EDITOR OF THE MEDICAL CIRCULAR.

SIR,—Can you inform me at what British or Foreign Universities, with exception of London University, the degree of M.D. can be obtained without residence? I am, &c.,

September 18, 1865. A GUY'S STUDENT.

[At no British University; and the degrees granted without residence at Foreign Universities are of no value, as they are not recognised by the Medical Council.—ED. MED. CIRCULAR.]

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL CIRCULAR.

SIR,—The following subscription has been further received on behalf of the above fund:—

	£	s.	d.
Erasmus Wilson, Esq., Henrietta street	2	2	0
Amount previously announced	125	9	9
Received at the 'Lancet' Office	9	9	0

Yours, &c.,

ROBERT FOWLER, M.D.,

145 Bishopsgate st. Without, Sept. 20, 1865. Treas. and Hon. Sec.

Salop and Montgomery Counties
LUNATIC ASYLUM

MATRON WANTED.

The Visitors of the above Asylum will also receive applications for the appointment of a Matron.

The Salary will be 60*l.* per annum with Board and furnished Lodgings in the Institution.

A Copy of the Rules of the Establishment can be had upon application to the Medical Superintendent at the Asylum, Bicton, Sherwsbury,

Applications stating Age and Testimonials to be forwarded to Mr. De Courcy Peele, Clerk to the Visitors, Shrewsbury, on or before Tuesday the 10th day of October next.

DE. COURCY PEELE, Clerk to the Visitors.

Salop and Montgomery Counties
LUNATIC ASYLUM.

MEDICAL SUPERINTENDENT WANTED.

The Visitors of the above Asylum, with a view to making an appointment to this Office, will receive Applications with Testimonials from such Medical Practitioners not exceeding forty years of age and duly registered to practice in Medicine and Surgery as may be willing to take the appointment.

The Person elected will be required to discharge the duties set forth in the statutes thereto relating, together with such as may be required by any rules or orders of the Visitors, having the aid of a duly qualified medical Assistant.

He must reside in the Asylum, where unfurnished apartments with Coal and Gas, will be provided by the Visitors, and must devote the whole of his time to the duties of the office, not engaging in any other professional or other business or employment. Salary 400*l.* per annum.

Applications with testimonials to be made to Mr. De Courcy Peele, Clerk to the Visitors Shrewsbury on or before Tuesday the 10th October next.

DE. COURCY PEELE, Clerk to the Visitors.

GENERAL MEDICAL COUNCIL.
32 SOHO SQUARE, LONDON, W.
September, 1865.

Registration at the Commencement

OF PROFESSIONAL STUDY.

NOTICE is hereby given, that Regulations for the Registration of Medical Students have been sent to all the recognised Schools of Medicine in England. Students commencing their studies are directed to apply to the Registrar for England, according to the Form with which they will be supplied on application to the several Qualifying Bodies, or at the Schools of Medicine and Hospitals.

Bethlem Hospital.—With a view of

extending the experience requisite for the efficient Medical Treatment and Management of the Insane, this Hospital is open for the admission of two Resident Medical Students who have recently obtained their Diplomas to practise Medicine and Surgery.

They will be permitted to reside in the Hospital for a term, generally not exceeding six months, and will be provided with such apartments, rations, and attendance as the Committee shall consider reasonable.

They will be under the direction of the Resident Physician, and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory.

Applications for the appointments, with testimonials, to be forwarded to Bridewell Hospital, Blackfriars, E.C., addressed to A. M. Jeaffreson, Esq., on or before Monday, the 9th of October next.

The election will take place on the 16th of October, and the elected candidates will be expected to commence residence on the 1st of November.

A. M. JEAFFRESON, Clerk.

September 2, 1865.

The London Hospital Medical

COLLEGE.—The next WINTER SESSION will commence on Monday, October 2nd, 1865, when the Introductory Lecture will be delivered by Mr. RIVINGTON, at 3 p.m.

General fee to Lectures and Hospital Practice, 84 guineas, payable in two instalments of 42 guineas each, at the commencement of the first two Winter Sessions of attendance.

Perpetual fee to the Lectures alone, 50*l*.

Students can make special entries to Lectures or Hospital Practice.

MEDICAL OFFICERS.

Consulting Surgeon—Mr. Luke.
Physicians—Dr. Fraser, Dr. Davies, Dr. Parker.
Surgeons—Mr. Adams, Mr. Curling, Mr. Hutchinson.
Assistant Physicians—Dr. Andrew Clark, Dr. Ramskill, Dr. Down, Dr. Hughlings Jackson.
Assistant-Surgeons—Mr. Maunder, Mr. Couper, Mr. Little, Mr. Rivington.
Obstetric Physician—Dr. Head.
Assistant Obstetric Physician—Dr. Palfrey.
Dental Surgeon—Mr. Barrett.

LECTURES AT THE LONDON HOSPITAL MEDICAL AND SURGICAL COLLEGE.

Medicine—Dr. Herbert Davies, Dr. Andrew Clark, and Dr. Ramskill.
Surgery—Mr. Hutchinson.
Descriptive and Surgical Anatomy—Mr. Adams and Mr. Little.
Physiology, General and Morbid Anatomy, and Practical Histology—Mr. Couper and Dr. Hughlings Jackson.
Practical Anatomy—Mr. Little and Mr. Rivington.
Chemistry and Practical Chemistry—Dr. Letheby.
Anatomy and Pathology of the Teeth and Dental Surgery—Mr. Barrett.
Midwifery and Diseases of Women and Children—Dr. Ramsbotham.
Forensic Medicine—Dr. Ramsbotham and Mr. Rodgers.
Materia Medica and General Therapeutics—Dr. Down.
Ophthalmic Surgery—Mr. Hutchinson.
Botany—Dr. Dresser.
Comparative Anatomy—Mr. Rivington.
Special Operative Surgery—Mr. Maunder.

The London Hospital contains 415 beds, and receives an average of more than 4,000 in-patients annually.

The Appointments of Dresser, House-Surgeon, Resident Medical Officer, Assistant-Medical Officer, Resident Obstetric Assistant, &c. &c., are open to the Students without further fee, and include residence and partial board.

Two Scholarships, the Duckworth Nelson Prize, and two Gold Medals will be awarded by competition during the ensuing Session.

Further particulars can be had on application to Mr. Hutchinson, Hon. Loc. Sec., 4 Finsbury circus, E.C., or at the College.

Mile-end, August 15th, 1865.

Royal Free Hospital.—Winter Ses-

SION, 1865-66.—The Pathological Practice of Surgery will continue to be demonstrated at the Bedside and in operations, on Wednesdays and Saturdays, at 2 P.M. by FREDERICK JAMES GANT, F.R.C.S., Surgeon and Pathological Anatomist to the Hospital.

Royal Free Hospital.—Winter Ses-

SION, 1865-66.—Practical Instruction in Surgery to First Year Students, and Dresserships to Students, after two years' Professional Education, both in accordance with the recent Regulations of the Royal College of Surgeons of England, may be obtained at this Hospital.

For particulars apply to

THOMAS STRANGEWAYS, Registrar.

Sydenham College Medical School,

Summer Lane, Birmingham, (opposite the General Hospital.)—The SESSION 1865-6 will COMMENCE on TUESDAY, October 3rd, at Three P.M., with an INTRODUCTORY ADDRESS by Mr. FURNEAUX JORDAN.—A Prospectus, containing full particulars will be sent, and further information obtained on application, either personally or by letter, to the Principal, Dr. Bell Fletcher, Waterloo street; the Treasurer, Dr. Russell, Newhall street, who is authorised to enter Students; or to the Secretaries, Mr. Bassett, Hockley Hill, and Mr. Howkins, Bennett's Hill, Birmingham.

St. Mary's Hospital Medical School.

The WINTER SESSION 1865-66 will commence on Monday, Oct. 2nd, at 8 o'clock P.M., with an Introductory Address by Dr. HANDFIELD JONES, F.R.S.

At this Hospital the Medical Appointments, including five House Surgeoncies, the annual value of which exceeds as many Scholarships of 50*l* each, and a resident Registrarship at 100*l* a year, are open to the pupils without additional fee. To enter, obtain prospectus, and for other information, apply to any of the Medical Officers and Lecturers, or to

ERNEST HART, Dean of the School.

Westminster Hospital School of

MEDICINE. The Introductory Address of the Session 1865-66, will be delivered in the Lecture Theatre, by Mr. BARNARD HOLT, F.R.C.S., on Monday, the 2nd of October, at 8 P.M. After the Address a Conversazione will be held in the Board-room of the Hospital. The Westminster Hospital was instituted A.D. 1719, and Incorporated by Act of Parliament, A.D. 1836. It contains 200 beds, and affords relief to about 28,000 out-patients annually.

HOSPITAL PRACTICE.

Physicians—Dr. Basham, Dr. Fincham, Dr. Radcliffe.
Assistant-Physicians—Dr. Anstie, Dr. Gibb, Dr. Willis.
Physician Accoucheur—Dr. Frederic Bird.
Surgeons—Mr. Barnard Holt, Mr. Brooke, Mr. Holthouse
Assistant-Surgeons—Mr. Hillman, Mr. Power, Mr. Heath
Surgeon-Dentist—Mr. Walker.

LECTURES.—WINTER SESSION.

Descriptive and Surgical Anatomy—Mr. Christopher Heath.
Practical Anatomy—Mr. W. F. Teevan.
Physiology and Physiological Anatomy—Mr. Power.
Chemistry—Mr. A. Dupre, Ph.D.
Medicine—Dr. Basham.
Surgery—Mr. Holthouse,
Dental Surgery—Mr. Walker.

SUMMER SESSION.

Botany—Mr. Syme, F.L.S.
Materia Medica and Therapeutics—Dr. Anstie.
Forensic Medicine—Dr. Gibb and Dr. Willis.
Midwifery—Dr. Frederic Bird.
Practical Chemistry—Mr. A. Dupre, Ph.D.
Comparative Anatomy and Zoology—Mr. Power.
Natural Philosophy—Mr. Brooke, M.A., F.R.S.

Clinical Lectures will be delivered weekly during the Winter and Summer Sessions by the Physicians and Surgeons.

PRIZE APPOINTMENTS AND PRIZES.

The offices of House-Physician and House-Surgeon are open to competition amongst gentlemen who have been educated at the Hospital, and who are qualified to practise under the Medical Registration Act. The House-Physician and House-Surgeon are not only appointed without the payment of any fee, but they are provided with board and lodging in the Hospital free of expense.

The Assistant House-Surgeon is appointed without fee from among the senior students by examination, and is provided with commons at the Hospital table.

Clinical Clerks and Dressers are selected from the most qualified students without additional fee.

The entire course of study (including Hospital Practice and Lectures) required by the Colleges of Physicians and Surgeons and the Society of Apothecaries may be attended on payment of 7 guineas, in three instalments. Perpetual, 80 guineas. Further information may be obtained on application to Mr. Power, 3 Grosvenor terrace, Pimlico, or to any of the Lecturers at the Hospital.

Second edition, corrected and revised, post free 7d., in cloth 10d.,

The Teeth: a Practical Treatise;

with the best Means of Restoring them when Defective or Lost. By A. ESKELL, Surgeon-Dentist, of Grosvenor Street, W. "We cannot do better than recommend for general perusal Mr. Eskell's treatise, which is as useful as it is unpretending."—'Telegraph,' June, 20th, 1865.

Sold by Simpkin and Marshall, Stationers'-hall-court.

NEW EDITION.—POST FREE.

Gabriel's Pamphlet on the Teeth,

(ILLUSTRATED AND DESCRIPTIVE.) Explaining the only effectual mode of supplying Artificial Teeth without pain, to answer in every particular the purpose of natural masticators. These Teeth are supplied on the principle of capillary attraction and suction, thus dispensing entirely with springs, and are supplied at moderate charges.

MESSRS. GABRIEL, THE OLD-ESTABLISHED DENTISTS.

PARISIAN MEDICAL NEWS.

Electric Properties of Mineral Waters.

During the past month the Academy of Science has re-ived numerous communications on subjects connected th Medicine. We will more especially advert to those warded by MM. Scoutetten, Boudin, and Amédée Paris. The very mention of M. Scoutetten's name implies an usion to electricity and electric action of mineral waters, plication of electric agency to the treatment of disease, electro-type, &c. Neither years nor contradiction can il to damp the ardour of this earnest investigator. In n has M. Schnepp, the assistant-inspector of Eaux nnes, presented to the Institute a memoir, in which he nonstrates, by direct experiment, that the waters of ne, conveyed away from the springs and preserved for eriod varying from a few months to five years, produce the skin and the fluids of the system electric phenomena cisely similar to those produced by the same waters ing from the spring; M. Scoutetten still persists in an osite opinion:—

Mineral waters," says he, in a paper read to the demy by M. Decaisne, "differ considerably from pump iver water; they are active *living* waters, and possess liar dynamic virtues; river water, on the contrary, is *statical* condition—its ingredients are at rest, and have luded all their chemical operations, hence they are in-ed with no electric power whatever.

When mineral waters have escaped from the spring, gradually lose their energy, because the chemical binations between the mineralising ingredients gra-ly cease, and they, therefore, preserve a portion only eir medicinal value. . .

This interesting and delicate inquiry has long occupied mind, and has induced me to undertake numerous re-ches and journeys; I have recently again travelled over ergne, and visited Royat, Saint Vectaire, La Bourboule, Mont-Dore, where I remained three weeks, and where lituted a series of experiments in the presence of the cal practitioners attached to the thermal establish-s. At my request, they formed themselves into a mittee for the purpose of testing the correctness of the brought forward in my work, 'On the Electric Action neral Waters,' and I now communicate to the Academy esults of their inquiry.

The committee was presided over by Dr. Vernière, the ector of the springs, and consisted of MM. Boudant, lot Mascarel, Payot, Brochin, chief editor of the ette des Hopitaux,' of Paris, who kindly undertook uties of Secretary, and M. Herpin, of Metz, the author veral valuable works on mineral waters, also lent his ble assistance."

e experiments lasted three days, and their results are died in a carefully prepared report drawn up by M. in, confirming the statement adduced twelve months y M. Scoutetten—namely, that "the electric mani-tions (in which reside the chief curative power of al springs), become weaker in proportion to the length me which has elapsed since the escape of the water the wells." It is, of course, impossible to refuse to credence to phenomena attested to by observers so worthy, but we cannot help inquiring how it happens the results attained by M. Schnepp, who is, un-tedly, a competent authority in such matters, have so widely different? This discrepancy of opinion is accounted for in the paper read by M. Decaisne.

a report of the transactions of learned societies, is bstract of another memoir sent in by M. Scoutet-based on eighteen cases, which show that the electro-method resorted to with perfect success by M. Nélaton in a case of nasal polypus, is also applicable to the destruction of a host of soft tumours containing liquids capable of being resolved into their constituent elements.

Asphyxia from Drowning; a New and Simple Method of Artificial Respiration.—A perusal of an article, in which you reproduce the official instructions published by the British Admiralty for the purpose of promulgating a knowledge of the kind of assistance most likely to prove serviceable to the drowned, induces me to communicate a mode of restoring respiration which is more simple, and, in my opinion, as efficient as the plans proposed by Marshall Hall and Dr. Sylvester.

The following is the system I have adopted:—

The operator standing opposite to the patient, whom we may suppose to be either in a recumbent or a sitting attitude, inserts the fore and middle fingers of each hand beneath the short ribs, forcing up the skin as far as possible in order to obtain a greater purchase. It is in the part corresponding to the union of the epigastric region with the hypochondrium in the lowest part of the chest that the power should be applied. The thumb lying on the outer surface of the short ribs includes them in a strong grasp. The thorax should then be viewed as a bellows, of which the ribs represent the alæ, and an alternating opening and closing motion, which, on account of the curvature of the ribs, is also converted into a rising and falling action of the chest, causes expansion and contraction of the respiratory apparatus. Extreme obesity alone might cause some embarrassment to the operator, but the procedure is in general extremely simple, and I have found it perfectly successful in a large number of cases.

In support of my assertion, I might adduce an instance of drowning in which I obtained, twenty-four years ago, unhoped-for results from this plan. Two years since, I again derived great benefit from the procedure in a case of asphyxia, consequent on the action of chloroform in a very stout woman, whose breast I had just removed. The cancerous tumour had been extirpated, but the anæsthesia persisting in an alarming manner, in spite of the various measures usually recommended to restore animation, I applied my system of artificial respiration, and the patient was immediately revived.

De Chilly, M.D. (*Vaucouleurs*).

The method advocated by our learned correspondent is extremely ingenious, and is certainly more rational than Marshall Hall's plan, which consists in a rolling motion imparted to the entire body. It is obvious that, turning the patient on the side and then on the abdomen, can in no wise increase the diameter of the chest, and that no elevation of the ribs can thus be effected. In the second place, in the prone attitude, liquids may obstruct the nose or fauces, and, in the rolling motion of the body, the contents of the stomach may readily flow into the œsophagus, and thence into the air-passages. In addition, the series of operations required are extremely fatiguing to the operator.

Dr. Sylvester's method is far preferable, and the movements imparted by this system efficiently enlarge the chest by causing elevation of the ribs, thus promoting the formation of a vacuum which the external air is at once called in to fill. In his comparison of both systems (*Annales de Médécine Navale*), M. Leroy de Méricourt observes, that Dr. Sylvester's plan was tried on dead subjects, and thus, by means of an indicating apparatus, it was ascertained that ten times more air was admitted into the chest than by Marshall Hall's method. Hence, we may infer that this physiologt's procedure, if not altogether set aside, at least should not occupy the first place assigned to it in the instructions of the Admiralty, and that practitioners will henceforth have to choose between Dr. Sylvester's system and that recommended by Dr. de Chilly.—'Journal of Practical Medicine and Surgery.'

Surgery in Kabylia.

M. A. Paris presented to the Academy a highly interesting memoir, entitled *The Application of the Trephine by the Native Surgeons in the Province of Constantina.*

As M. Guyon remarked, in his analysis of this paper, the

Kabyles perform a large number of serious operations, and their system of bandaging in fractures is perfect. They have, from time immemorial, been acquainted with the starch bandage, and they apply it not only to man but to animals. They tighten the bandage, however, too much, and gangrene of the limb is the not unusual consequence. Hence, when death is not the result of the efforts of nature to separate the mortified parts, portions of bone frequently protrude beyond the cicatrix, and French surgeons have often been called on to perform excision. The Kabyles operate for cataract, not on the human subject only, but on cattle, and more especially on sheep.

Trephining of the bones of the skull is viewed by the native surgeons of the Aouress district as an unimportant operation, or, at least, as a procedure unattended with peril to life. The author, in illustration of this opinion, relates a circumstance which occurred in 1859, and which would afford fresh proof, were any needed, of the great love of the natives of this part of Africa for money. A native of the tribe of the Beni-Ferrah was in a general affray beaten by another, and received blows on every part of his body except his head. He was of course entitled, as we should term it, to damages; but in order to increase the amount of his claim, he feigned great suffering in the head, and got himself trepanned. After his recovery, his adversary appealed from the award made by the judge, and contended that no blows whatever had been inflicted on that part of his person. An inquiry was set on foot, the fraud was discovered, and the beaten man, as well as the operator who had assisted him in carrying out the imposition, were both severely punished.

The application of the trephine, which in this instance was in all probability superficial, consists in the perforation of a square aperture through the bones of the skull. Four incisions are previously performed with an old razor or a bill-hook, and a corresponding flap removed, so as to expose the bones. The orifice is afterwards protected with a concave copper disc, pierced with numerous holes, to facilitate the escape of the suppuration, and secured to the head with appropriate strings.

The author was extremely desirous to preserve the instruments, of which he was allowed to take a sketch; this, however, was not permitted, "these appliances being invested with a sacred character, and being, moreover, the exclusive property of a family of surgeons, in which they are transmitted as an heirloom, together with instructions for their use."

It is to be regretted that, in his report on the paper sent in by Dr. A. Paris, M. Guyon should have omitted to describe the circumstances deemed by the Arabs to require the performance of the operation, although it appears, from his remarks, that the procedure is resorted to for many various injuries of the head, and often for very trifling wounds, in accordance with theoretical views, which it would have been interesting to be acquainted with.

THORACENTESIS.

Thoracentesis, a subject exhaustively discussed a twelvemonth ago at the Medical Society of Hospitals, is again on its trial at the Academy of Medicine. We should, however, remark that the subject of inquiry is not so much the active utility of the operation, as the best mode to be adopted for its performance. The present debate originated in a communication made by M. Piorry in April last, in which he advocated a new method, consisting in tapping the chest under water, so as to obviate the possibility of the penetration of air into the pleura.

M. Jules Guérin's peculiar researches in some measure obliged him to take advantage of this opportunity again to invite attention to the benefits of subcutaneous operations, and he did not fail to do so. In his remarks, however, he did not award to Reybard's method the full meed of praise to which it is legitimately entitled. We have witnessed, in upwards of a score of cases, the performance of the operation by Messrs. Trousseau and Aran with Reybard's canula, and in no instance did a particle of air penetrate into the chest, the formidable accident most dreaded by M. Guérin. M. Piorry proposes the use of an india-rubber siphon, immersed at its extremity in a basin of water, assuredly an ingenious suggestion, but less simple than the procedure recommended by the Lyons surgeon. —'Journal of Practical Medicine and Surgery.'

EPIDEMIOLOGICAL SOCIETY.

CHOLERA.

MEMORIAL TO THE PRIVY COUNCIL.

To the Editor of the Medical Circular.

SIR,—I beg to submit to you the accompanying memorial respecting epidemic cholera, which was laid before the Lord President of the Council by a deputation of the Council of the Epidemiological Society this morning.

The deputation consisted of Dr. Milroy (President), Dr. Babington, F.R.S., Dr. Daller Lewis, Dr. Camps, F.S.S., F.L.S., and myself. I am, Sir,

Your obedient servant,

J. N. RADCLIFFE.

70 Guilford street, Russell square, W.C.,
Sept. 25, 1865.

The Epidemiological Society, ever since its formation immediately upon the cessation of the Epidemic of Cholera in 1849, has had its attention in a special degree directed to the investigation of the disease as it has appeared both in this country and abroad. Many of the original members had been engaged in carrying out the inquiries instituted by the General Board of Health during that visitation, and were again employed on like duties in the Epidemic of 1853-54. Other members have had extensive experience of the pestilence in the East Indies and other tropical countries; and, in almost every session, communications illustrative of its characters have been read and discussed at the meetings of the Society.

From the earliest intelligence of the present epidemic whan it appeared last June in Egypt, its history has been sedulously watched by a Committee, for the purpose of comparing its course with that of the former European epidemics which, after ravaging various countries on the Continent, at length reached our own shores; and with a view of forming such practical conclusions as might guide the mind of the profession, and of the public generally, in regard of the precautionary measures best calculated to protect the country against an invasion, and—if that should fail—to mitigate to the utmost its destructive effects among the people.

With respect to any endeavour to exclude Epidemic Cholera by the system of quarantine such as was formerly practised in this country, and as it is still adopted and being carried out at the present time in all the Mediterranean seaports, the experience of the visitations in 1847-8, 1848, and 1853 appears to show conclusively that no reliance whatever can safely be placed upon it to keep off or avert the pestilence. Moreover, while the adoption of quarantine serves to give delusive hopes to the public mind, it generally leads to the unwise postponement of those internal measures of local improvement which afford the surest defence against the dangers of the assault. Sanitary precautions *within* a place are far more important than military cordons *without*.

While discountenancing the practice of an enforced detention and segregation, for a specified number of days, of all arrivals from an infected country—irrespective of the condition of the vessels themselves and of the persons on board, whether the former be thoroughly clean and airy or foul, close, and crowded, and whether the passengers and crew be sick or quite healthy—the Council of the Epidemiological Society are, at the same time, strongly of opinion that the interests of the public health require that efficient sanitary supervision should be exercised in all the chief sea and river-port towns, and that the most beneficial results not only to these places themselves but to the country generally may be expected, on the threatened advent of an epidemic, from the timely adoption of such a precaution

It is to be observed that, in the successive visitations of the cholera in this country, the disease always manifested itself first on or near the sea-coast, and in some large busy port.

In 1831, the earliest cases occurred in Sunderland during September, and Newcastle was attacked about three weeks later.

In 1848, the disease seems to have appeared about the end of September in several places on the east coast—viz.: Hull, Sunderland, Edinburgh, and the metropolis—at nearly the same time.

The visitation of 1853 may be said to have commenced with the outbreak at Newcastle in the month of September, which proved so destructive to life, and so hurtful to the commercial interests of the town.

Besides the marked tendency in Epidemic Cholera to appear first on, or near to the coast, it is also to be observed that many of our seaport towns have suffered with unusual severity in more than one of the visitations—witness, Newcastle, Sunderland, and Hull—Glasgow, Liverpool, and Bristol—Plymouth, Portsmouth, and Southampton—Sheerness and London. The damp low sites of the worst parts of these towns, always in the vicinity of their harbours and docks (which are in themselves often prolific of malarious effluvia), together with the filthy and crowded dwellings to which seamen generally resort, and their reckless intemperate habits, cannot fail to aggravate other sanitary evils, and greatly to increase the predisposition of a maritime population to epidemic influences. The unfavourable state of the health, too, among the crews of many merchant ships upon their arrival, in consequence of the neglect of hygienic precautions during the voyage, renders them peculiarly susceptible of a poisonous atmosphere in the port; and there is good reason to believe that on several occasions where the earliest cases of an epidemic disease have occurred among persons recently arrived, this has been due rather to the cause just mentioned than to those persons having imported the disease from abroad. In the case of river-ports becoming infected, the disease, from its tendency to follow the line of water communication, has often been observed to make its way thence upward into the interior of the country.

In view of these considerations, the Council of the Society beg respectfully to state that in their opinion it is highly desirable, for the welfare of the kingdom generally, that a sanitary inspection be made of the principal sea-port towns to ascertain their actual condition, more especially of their harbours, docks, shipping, dwellings for seamen, etc., and with the view of discovering what provisions or arrangements exist for the reception and treatment of cases of sickness in ships upon their arrival from abroad, in the event of the cholera making its appearance in the port.

With regard to the health-condition of the general population, the Council take leave, with great respect, to express their entire concurrence in the fitness of the timely precautionary instructions which have been already promulgated by the Privy Council;—and, while they are well aware of the insufficiency in many respects of the existing laws for the prompt and effectual correction of numerous sanitary evils which seriously endanger the health of the humbler classes at all times, and especially in an epidemic season, they leave with confidence to the wisdom of the Government to determine the time when it may be necessary, by the issuing of a special order, to confer upon local authorities larger and more summary powers for the prevention of disease and the protection of the public health.

Gavin Milroy, M.D., F.R.C.P., *President.*
J. N. Radcliffe, *Secretary.*
September, 1865.

The Drainage of Portsmouth.—The ceremony of laying the foundation-stone of these important works took place at Eastney, near Portsmouth, on Tuesday, in the presence of the mayor, the principal members of the corporate body, and a few ladies and gentlemen.

ADULTERATION OF FOOD.

Annexed year by year to the Inland Revenue comes a communication from the Principal of the Laboratory which tells some little of the story of the adulteration of articles of food. It is a chapter of the history of invention and adroitness in the acquisition of wealth by fraud. Perhaps no article subject to revenue duties is more "sophisticated" than pepper. It may be mixed with its own weight of almost worthless ingredients without being rendered unsaleable on the score of want of pungency. The following case, which has occurred in the past financial year, shows the cautious manner in which adulterated pepper is passed into consumption through the agency of the retailers. A supervisor in a remote part of Scotland purchased from a retailer a sample of pepper which appeared to him to be adulterated. After expressing his doubts to the trader (a woman) as to the genuineness of the article, she replied that her opinion was that the pepper was, "not what it ought to be." She also gave the name of the dealer in Glasgow who supplied the article, and produced the invoice, in which this so-called pepper was described, no doubt with a view to escape the consequences of detection, as "capsicum," which is a legitimate article of commerce. At the same time she mentioned the name of another retailer in the neighbourhood who was supplied by the same dealer, and on visiting his premises the supervisor made another purchase. Of these samples the first was found to consist of 25 per cent. of gypsum, the rest being mustard husks and a little cereal starch, and, though a good imitation of pepper, it did not contain a trace of that article. The second sample consisted of 16 per cent. of gypsum, 44 per cent. of mustard husks, a little cereal starch, and the rest pepper. The supervisor in Glasgow was directed to visit the premises of the dealer who supplied the above retailers, and, on doing so, purchased a sample of black pepper, and a sample of an article much resembling pepper, which the dealer called "capsicums." The black pepper was found to be genuine, but the "capsicums," consisted of 6 per cent. of sand, 5 of gypsum, a little starch, the rest being mustard husks. It contained no capsicum. The dealer had no licence to deal in pepper, and stated that he received his stock from a wholesale druggist in Liverpool, but on the inspection of the premises of the latter by the officers in Liverpool no adulterated pepper, nor any substance prepared to imitate pepper, could be found. The dealer in Glasgow was prosecuted and convicted for selling pepper without a licence, and for having in his possession an article prepared to imitate, and intended to be used as, pepper. Coffee is another article much adulterated. There are good reasons for believing that it is now being extensively sold mixed with large proportions of burnt sugar or caramel, a substance of comparatively little value, but one which enables the dealers to command a higher price for coffee containing it than they could obtain for the coffee alone, some of them selling the mixture at even 2s. per lb. Measures are being taken for the suppression of this fraud. The most usual mode of adulterating beer, and one which, says the Principal of the Inland Revenue Laboratory, there are good grounds for believing is very generally practised by the publicans in London, is to add water to the beverage, the injury to the fulness or "body" of the article arising from this dilution being repaired by the introduction of sugar, treacle, or other saccharine matter—a description of fraud the commission of which cannot, in the present state of chymical knowledge, be satisfactorily proved by analysis. Within the past year thirty-one samples of beer and of materials used by brewers were examined and of these twenty-three were found to be illicit. In thirteen instances grains of paradise had been used, and in one that drug in conjunction with coriander seeds; in four coriander seeds alone, and in one those seeds with a large proportion of white mustard seeds; two samples contained sweet flag (calamus aromaticus), and another sulphate of iron. No detection of the illicit use of cocculus indicus, tobacco or other poisonous substances was made. The stringent measures adopted by the Customs to prevent the importation of simulated wines are still continued, and 182 samples have within the year been examined, of which 102 were found to be composed chiefly of factitious wines, while

nearly the whole of the remaining eighty were of very low value, and, although genuine wine predominated more or less in their composition, they still contained considerable proportions of spurious wine. There can be no doubt but that these made-up liquids would have passed into consumption either *per se* as sherry, or mixed with genuine wine. A few instances have been discovered of the sale of drinks under the names of "Indianna brandee," "medicated whiskee," "pure Islay mountain," "Indian tincture," and "red currant cough elixir," the exciting principle of all of which was found to be hyponitrous ether prepared from methylated spirit. The above compounds were all highly stimulating, and it would appear that they are consumed by some of the poor, because they produce intoxication at the cost of only a few pence, while there are good reasons for believing that hyponitrous ether itself, and in some parts of Ireland even sulphuric ether, are used by the needy classes for the same object. It is difficult to see how this evil, so pernicious to the moral and physical welfare of those who indulge in it, can be checked, as the substances under consideration possess more the character of medicine, than of ordinary spirits, and may thus be legally kept and sold by any chymist. In such cases all that can be done is to cry, "Buyer, beware." But in view of so many adulterations it is satisfactory to learn that in the educational branch of the laboratory fifty-nine students have now passed through a course of education in chymistry, forming a valuable reserve from which officers may be selected for the Inland Revenue service, and 170 examiners have received a month's instruction in the modes of detecting adulteration.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

JULY 5TH, 1865.

DR. BARNES, PRESIDENT.

DR. BATHURST WOODMAN showed a

DERMOID CAST,

removed after death. It was attached to the right ovary, apparently in the situation of the pons ovarium. The ovary itself was converted into an enormous polycystic tumour, larger than the gravid uterus, filled with colloid matter, in which a few cells, many nuclei, granular matter, and exudation corpuscles in great abundance were found. There were no evidences of malignancy. Ovariotomy would have been performed by Mr. Couper, but, apparently from the bursting of one or two of the cysts, peritonitus set in, and killed her before the operation could be done. Her age was forty-seven, a married woman, living separate from her husband. Two attempts had been made at tapping some weeks before death, but the colloid matter would not run through the trocar. The dermoid cyst had been turned inside out, displaying two rudimentary teeth and hairs growing from the inside. The contents were hair and sebaceous material.

MR. WAITS recited a case of Hydroencephalocele of great size in which tapping was practised, the child living about our months.

DR. AVELING exhibited a doubled-curved Hysterotome which he had invented some time since, but which he had now discarded. (*a*) Because incisions could only be made by it in a lateral direction. (*b*) Because the two blades did not cut to an equal depth, the yielding structures being deeply incised and the denser ones remaining merely scarified. He also showed the single straight Hysterotome which he now uses. By pressing a handle the blade is projected so as to enable the operator to make an incision increasing in depth from the internal os to the external. Dr. Aveling also exhibited a Spring Tent which he uses after the operation to keep the uterine canal open.

THE PRESIDENT thought Dr. Aveling's hysterotome an improvement upon Prof. Simpson's, as the hinge of the blade was at the end of the instrument instead of in the middle. He would, however, ask Dr. Aveling whether there would not be some difficulty in passing the uterine portion of the instrument through a strictured os?

DR. AVELING stated that he never used the slightest force in introducing the hysterotome, but, when necessary, always first passed a small tangle tent, which in a few hours temporarily dilated the canal.

MR. ELLIS gave the particulars of a Case of Monstrosity occurring in two children (twins), in both of whom the nose was represented by a short trunk. In one the eyes were totally absent, but in the other they were present.

Mr. TRUMAN read a report of a

FATAL CASE OF TUBAL EXTRA-UTERINE FŒTATION,

to which was added the microscopical examination by Dr. Braxton Hicks. Death took place from sudden rupture of the tube at the end of the third month of pregnancy.

Mr. ROPER remarked that in the two cases of tubal pregnancy which had occurred in his practice, complete rupture of the cyst took place at the seventh or eighth week of pregnancy, and death rapidly followed from hæmorrhage into the peritoneal cavity. Coincident with the first symptoms in each case there were symptoms of menstruation. He believed that when the ovum was in the free part of the tube (not that part which passes through the uterine wall), rupture, partial or entire, might be expected at the seventh or eighth week of pregnancy, as at this period the ovum became so large that the tube would not allow of further distension without giving way; it was therefore at this period that we might look for the first symptoms of the accident. Diagnosis of the nature of the case would be importantly confirmed by noting the time at which the first symptoms happen (whether at a catamenial period), and the actual existence of a menstrual discharge. The uterus being unoccupied, the discharge might be regarded as truly menstrual, coming from the lining membrane of the uterus; and the increased functional activity of the reproductive organs at this particular period, the additional afflux of blood, and the turgescence of the vessels concerned in nourishing the ovum, were coincident circumstances likely to determine or hasten rupture.

THE PRESIDENT called attention to the fact that previously to the rupture of the cyst—that is, previously to the shock and collapse which mark the epoch of rupture—it was usual to observe a discharge of blood per vaginam. The hæmorrhage he believed was commonly produced in this way: The ovum growing at about two or three months, the period when chorion is rapidly forming placenta, the rate of growth of the villi greatly exceeds that of the sac. The Fallopian tube is unfitted to harbour the ovum; it cannot keep pace with the shooting-out of villi. These become detached, and hæmorrhage results. Then, under combined distension from growing ovum and hæmorrhage, rupture takes place. It was by a perfectly analogous process, in his (Dr. Barnes's) opinion, that hæmorrhage took place in placenta prævia. Here is an *error loci*, as in tubal pregnancy: the ovum grows in the wrong place. The cervical zone is not well adapted to grow with the growth of the ovum. Hence a time arrives, about the fifth or sixth month generally, when the shooting villi get detached from the uterine wall, and hæmorrhage results. This explanation the President observed, differed entirely from the theory generally received, which attributed the hæmorrhage to the lower segment of the uterus growing away in some manner from the ovum. The cases of tubal gestation and placenta prævia were strictly analogous in this respect. Both were examples of ectopic gestation: the ovum growing in a structure not fitted to grow in proportion with it.

DR. PLAYFAIR asked whether Dr. Barnes thought that either with the assistance of the symptoms he had pointed out or by any other means, he considered it possible to arrive at the diagnosis of a tubular fœtation before rupture had occurred. There could be no doubt that the question of diagnosis was one of extreme importance, because if the existence of a Fallopian pregnancy could be ascertained with a tolerable degree of certainty, it might perhaps be possible to adopt some method of treatment which would save the patient from the almost certainly fatal results following rupture. Thus, for example, it might be worthy

of consideration whether the operation of gastrotomy and the ligature and removal of the Fallopian tube and its contents might not be successfully resorted to. The risk from such an operation would be infinitely less than that which follows the rupture of the cyst. At present the difficulties of diagnosis are undoubtedly almost insuperable ; but Dr. Barnes' interesting observations seemed to indicate a means by which they might in time be lessened or overcome.

Dr. Braxton Hicks thought the collection of the histories and of the post-mortem examinations of such cases very valuable, inasmuch as it would help to guide us as to the possibility of operative interference, even if the diagnosis could be clearly made out. From what he had seen he thought in the majority of these cases there would co-exist circumstances, such as adhesions, &c., which would entirely prevent our getting below the sac, so as to tie it. Even many of the cases of tubal fœtation were caused by curving of the tube by old contractions or other causes, rendering any chance of benefit hopeless.

Dr. Playfair said that he believed, as a rule, extensive adhesions would not be found in cases of tubular fœtation before rupture had taken place. After the fœtus had escaped into the cavity of the abdomen, if the patient survived the shock of the rupture, an adventitious cyst was formed round it, which was usually extensively adherent to the surrounding parts ; and it would doubtless be very difficult to remove this *en masse* by gastrotomy ; although Mr. Spencer Wells, in a previous discussion on the subject, had suggested the possibility of this being done. But in a tubular fœtation before rupture he (Dr. Playfair) apprehended no such difficulty would be met with.

Dr. Graily Hewitt observed that the diagnosis of cases of the kind now under consideration was, and he believed always would be very difficult ; and he feared that but little reliance could be placed on the circumstance adverted to by the President—viz., the occurrence of hæmorrhage as a precursor of rupture, inasmuch as it was well known that in cases of extra-uterine pregnancy hæmorrhage from the uterus was not unfrequent, and that at periods some time antecedent to the rupture. With reference to the time at which rupture occurred in cases of Fallopian pregnancy, there was a very important fact to be borne in mind —viz., that, as Kussmaul had pointed out, many cases of supposed Fallopian pregnancy were really cases of bicorned uterus ; and the difference in the result between such a case and one of Fallopian pregnancy with a normal uterus was necessarily very great. In the one case, rupture at a comparatively early period usually occurred ; whereas in the other the pregnancy might proceed normally.

Dr. Ritchie made some remarka on the interesting question of the period at which rupture of the sac usually occurs in tubal pregnancy. He referred to two cases which had been observed by a French accoucheur, where there was some reason to believe that the fœtus, after nine months of intra-tubal life, had been extracted by the natural maternal passages. He surmised that perhaps those cases were to be explained in the manner just referred to by Dr. Graily Hewitt : that they were perhaps instances of double uterus where the entrance to the second horn or loculus had been mistaken for the uterine orifice of the Fallopian tubes.

The President observed that the question now started —whether gastrotomy might not be performed *before* rupture of the sac—must greatly depend upon means of diagnosis. He did not think that the preliminary hæmorrhage to which he had called attention, even aided by other indications, could ever raise more than a strong presumption : the evidence could hardly be great enough to justify the operation. Again, rupture commonly took place not later than three months. He had performed post-mortem examinations in two such cases. In both there was great difficulty in discovering and isolating the parts concerned. In the living subject the task would often be impossible.

ANTEFLEXION OF THE GRAVID UTERUS.

Dr. Graily Hewitt related the particulars of a case now under his care, in which anteflexion of the uterus, which existed before pregnancy and which had been nearly cured, was found to be present at the fourth month of pregnancy, and to such an extent as to interfere with the rising of the uterus out of the pelvic cavity into the abdomen. He was called to see her at that time, and found the os high up in the vagina, and the body of the uterus tilted forwards and pressing deeply on the bladder ; the soft parts were greatly swollen, micturition exceedingly frequent, and acute pain was present. The patient was ordered to be in bed, and in three days the uterus was liberated from the pelvis, and the symptoms became relieved. Dr. Graily Hewitt believed that anteflexion of the gravid uterus was very rare, and he had not met with any description of it. In this case the patient had been previously treated by him for anteflexion, and this gave him at once a clue to the nature of the affection.

OBITUARY.

DR. GRABHAM OF ROCHFORD.

Another link in the chain that connects the present race of Medical practitioners with the past has been severed. The subject of this little sketch, who was well known in the southern division of the county of Essex, and more especially in the hundred of Rochford, where he practised, died on the 18th instant, after a long and honourable career. Born in the year 1794, near Bridgwater, Somerset, he was apprenticed, together with the late Mr. Wakley, to a Medical practitioner at Taunton. This gentleman having left the country soon afterwards, young Grabham completed his term with Mr. Leroux, a surgeon at Clifton, and at the same time became a pupil of Mr. Shute, one of the surgeons of the Bristol Infirmary. Soon afterwards he went to London, and entered the Borough hospitals, which were then united. Here he had the advantage of attending the lectures of such men as Sir Astley Cooper, the elder Cline, and Babington ; and so conspicuous were his diligence and zeal that the former great surgeon took him by the hand, and on his passing the Hall in 1816 and the College in 1817, he introduced him to Dr. Swaine of Rochford as a most eligible partner. Here he settled in 1817, and carved out one of the largest practices in the county.

Possessed of a wonderfully retentive memory, and a well-grounded knowledge of almost every scientific and literary subject, added to a kindliness of disposition and winning manner, it was no wonder that he became a favourite with all classes. He always contrived to keep pace with the times, notwithstanding his laborious practice ; and for the greater part of his life it was his wont to rise at daybreak, and quietly make himself master of any new book that had come out.

He was a sound and successful practitioner, and had often performed most of the capital operations of surgery. From his old friend Sir Astley he obtained many a " wrinkle ;" for he often corresponded with him, and more than once came down to visit his *protégé*. In 1852, finding his health failing, he retired from practice, taking with him a very tangible proof of the esteem of his friends. He afterwards took the M.D of St. Andrews, and the M.R.C.P. of London ; having also, in the year 1844, had the honorary F.R.C.S. given to him. Before closing this short notice, a remarkable instance of the force of good example and bringing up must be stated—namely that four of his sons became prizemen and house-surgeons of St. Thomas's Hospital, while another was a high wrangler at Cambridge. Of the late Dr. Grabham's private qualities it need only be added that he was a kind and affectionate husband, father, and friend.—' Lancet.'

Sanitary Doings in Bath.—At a numerously attended meeting of the Town Council of Bath, which was specially called to consider the propriety of appointing a Medical Officer of Health for the city, it was resolved that such an officer be appointed, there being only two dissentients. An amendment was proposed that no such appointment be made, which was rejected by twenty votes to two ! The subject of salary, etc., was deferred for future consideration.

REVIEW OF THE PERIODICALS.

The 'Lancet.'

Dr. Barnes continues his "Lectures on Puerperal Fever," his present subject being what he terms Thrombotic Puerperal Fever. He sets out by stating that there is a condition of the blood resulting partly from puerpery and partly from pregnancy, of which the chief feature is excess of fibrin, and the blood in this condition shows a remarkable tendency to coagulate in the vessels. The occurrence of what is called "phlegmasia dolens" is due to this condition, and the febrile states associated with it are what Dr. Barnes proposes to call Thrombotic Puerperal Fever. Arterial thrombosis, as is now well known, is one of the sequels of acute rheumatism, and is caused by the precipitation of fibrin upon the left cardiac valves; but in the majority of puerperal cases the thrombosis is venous. This is a fortunate circumstance, because arterial thrombosis is mostly fatal, while the venous form generally ends in recovery. The greater frequency of venous thrombosis, as compared with arterial is explained by the structure of the veins, the valves of which retard the blood-stream and thus offer the most favourable condition for the reaction which determines the precipitation of fibrin in the living vessels. In illustration of these views a case is recorded of phlegmasia dolens arising in a lady about a fortnight after delivery, but terminating in recovery at the end of about six weeks. In the treatment, local measures should be adopted for the relief of the swelling and pain, and leeches are commonly of great service in the first instance, followed by blisters; and the limb should be flexed and wrapped up in cotton-wool surrounded with oil-silk. After the acute stage has passed, frictions with oil or camphor-liniment are useful, but the friction should be very gentle. Generous diet is necessary, and wine should be allowed. Recovery is always tedious and it is doubtful whether veins which have undergone the distention and tortuosity consequent upon phlegmasia dolens ever perfectly regain their normal condition. ——Dr. A. H. Hassall contributes a paper "On Intermittent, or Winter Hæmaturia," two cases of which he has had lately under his care. The treatment consisted of the administration of astringents and tonics—viz., tannic and gallic acids, iron, and quinine. The microscopical examination of the bloody urine, showed the presence of albumen and of the colouring principle of the blood, but not of the blood corpuscles themselves.——Mr. Walter Hardin relates "A Case of Cæsarean Section," the patient having a distorted pelvis, from rickets. The operation was successfully performed, and the patient seemed to be doing well for two or three days, but unfavourable symptoms were afterwards developed, and she died. Mr. Hardin thinks that the patient would have had a better chance if she had had more care and better nourishment than fell to her lot in the after-treatment.——Dr. G. H. Phillipson relates "A Case of Fibrinous Concretions in the Pulmonary Artery." The case occurred in a female, who was near the end of her pregnancy, and had been suffering from a slight attack of bronchitis, from which however she had apparently quite recovered. She was in the act of opening her street-door, when she fell down and died in a few minutes. On a post-mortem examination, the cavity of the right ventricle was found nearly filled by a fibrinous concretion, which extended through the right and left divisions of the pulmonary artery, as far as they could be traced in the lungs. Dr. Phillipson remarks that although in women after delivery the pulmonary artery has sometimes been found plugged with a fibrinous coagulum, there are few cases of such a condition in advanced pregnancy.

The 'Dublin Quarterly Journal of Medical Science,' No. LXXIX. August, 1865.

The first article in this number consists of "Some Notes in Practical Surgery," by Dr. George H. Porter, surgeon to the Meath Hospital. The cases are divided into three classes, namely, four successful cases of stone in the urinary bladder removed by the operation of lithotomy; aneurism of the popliteal artery, cured by digital pressure in twenty-six hours and forty-five minutes; and a case of castration, in which the vessels of the cord were secured by acupressure. In the last case, the result of acupressure was quite successful in restraining the hæmorrhage, but Dr. Porter does not venture to recommend surgeons on all occasions to adopt this mode of closing vessels. He thinks the great objection that might be urged against this operation is its tediousness as compared with the ligature.—Dr. T. M Madden contributes the second article, which is "On the Climate of Malaga, and its Influence on Chronic Pulmonary Diseases, especially Consumption." Dr. Madden recommends invalids to take the route by Paris and Marseilles, and thence by steamer to Malaga, or to go direct by sea from Liverpool to Malaga. The hygienic condition of this town is stated by Dr. Madden to be very defective, and there is consequently a prevalence of zymotic disease; but he considers that in chronic pulmonary maladies, especially phthisis, Malaga is superior to any health resort in Europe, and inferior only to Western Australia and Upper Egypt.—Dr. Henry Kennedy offers "Some Remarks on Hydrocephalus, its Diagnosis, Prognosis, and Treatment," and after alluding to the difficulty often experienced in ascertaining the existence of the disease, he lays down certain rules for treatment, which, in his opinion, should consist in the application of leeches, and subsequently of blisters, and the administration of alterative doses of mercury. But he also gives wine, and thus his treatment consists both of the antiphlogistic and stimulant plans combined.—Dr. John Beddoe contributes an article "On Hospital Dietaries," in which he compares the dietaries of various hospitals, and also of prisons and lunatic asylums in the United Kingdom. In reference to the allowance of beer in hospitals he thinks it ought not to form a part of the regular diet, as it opposes the progress of temperance among the poor; and he adverts to the fact that in the Scottish prisons, where no alcohol is allowed, the standard of health is remarkably high. Dr. Beddoe then gives the results of some experiments made by him to test, by weighing patients and examining their urine, the sufficiency of the dietary of the Bristol Royal Infirmary. He thinks, upon the whole, that the dietary is sufficient, but that an increase in quantity would probably accelerate the cure of the patients.——Mr. Henry Wilson contributes "Some Ophthalmic Notes."——Dr. Robert McDonnell describes "A Case of Fracture of the Spine, in which the Operation of Trephining was Performed," and he illustrates his paper by a diagram of the fracture.—Mr. J. Wharton relates "Two Cases of Penetrating Wound of the Chest."——Dr. Frederick Kirkpatrick contributes "Some Observations and Cases setting forth the advantage to be derived from the Decided Use of Caustics in Certain Surgical Diseases, more particularly those affecting the Bones and Joints;" a plan which he thinks may be substituted for the difficult operation of excision, as in the carpus, and even in some of the larger joints.—Dr. Percival Wright contributes a short article "On Smith, Beck and Beck's Modification of Liebreich's Ophthalmoscope," and a plate is given representing the form of instrument recommended.

THE CHOLERA AT CONSTANTINOPLE.

The following letter appears in the 'Medical Times and Gazette':—

To all appearance we have arrived at the end of the cholera epidemic, for during the last week or so there have been only sporadic cases—viz., from thirty to forty per diem. We have thus at length got over two miserable months, and I may well say that at no previous time within men's memory have we ever had an epidemic of such

exceeding violence. The number of deaths amounts to about 40,000, most victims belonging, as usual, to the lower classes. In the commencement of August the daily mortality was about 1,500, and this ratio continued for eight or ten days. There are at present no trustworthy official statements about the number of deaths, for the daily bulletins which were published in the political journals were more intended to soothe the troubled mind of the people than to give reliable information, and, therefore, do not deserve any consideration whatever; but even if people in official quarters wished to tell the whole truth, this would be impossible, since a large number—I may almost say about one-half—of the cases have never been reported.

The violence of the present epidemic cannot be explained at all by local causes, since previous visitations of the disease have on the contrary, been very mild; thus, for instance, that of 1854 was scarcely worth mentioning when compared with the present calamity. This time the whole aspect of the case was different; a panic seized the whole population; everybody who could took to flight, some went to the country, others abroad, and, as is usual under such circumstances, the cholera followed and overtook those who had in vain endeavoured to escape from it. The city seemed to be depopulated; no business was done, all public institutions were closed, and even in the Government offices scarcely any work was performed. Funeral processions and transports of the sick were to be seen everywhere, and served to discourage even the boldest. I am thankful to say that all this is a thing of the past, and I will now endeavour to give you a short history of the epidemic according to the few reliable sources which have come to my knowledge.

There is not the slightest doubt that the epidemic was imported from Alexandria. The man-of-war Makbiri-Surur, a steamer which arrived here from Alexandria, put on shore twenty-one persons suffering from cholera on June 28 and 30. These were brought to the arsenal. Up to that time not a single case of cholera had occurred in Constantinople, and the general sanitary condition of the town had been excellent. On July 3 the first case of cholera was reported to have occurred amongst the marine soldiers, and since that time the number of cases in the arsenal, and in the men-of-war stationed before the same, increased from day to day. On July 10, numerous cases were recorded as having occurred bordering on the arsenal, and which is called Kissimparha. This quarter now became the starting-point from where the gradual infection of the whole town took place. These facts have been placed beyond doubt by the investigations of the chief Physician to the Marine Hospital, Dr. Mühlig, who has taken the greatest care to ascertain the course and progress of the disease. From Kassimparha, in the Golden Horn, the cholera made a great leap to Jenikoy, in the Bosphorus; it then appeared in Haskay and Jenishehir, both of which quarters border on Kissimparha. It was then brought by fugitives to Kurkunshuk, on the Asiatic side of the Bosphorus; and the whole of Stamboul, Therapia, and Scutari were fearfully visited. In fact, no quarter was spared, even the Princes' Islands and the Asiatic coast opposite to them were invaded. In almost all these cases the infection could be traced directly to fugitives who had come from some of the focuses previously mentioned. As a rule, there were only very few cases in every such quarter for the first few days, after which, in a single night, countless victims fell as by one stroke of the Avenging Angel; then everybody took to flight, the dead were left unburied, and the sick were deserted by their relatives. For some days subsequently a few more cases occurred, and gradually such local epidemics seemed to burn themselves out. The same course which the scourge thus pursued in whole quarters of the city was also observed in single streets and houses. At first the disease is imported, there is a case or two, suddenly there is immense mortality, and then it gradually diminishes. A single case in one house was quite the exception; there was generally several, and in some instances the whole population of a house has literally been swept away.

The character of the epidemic was very severe throughout, since a large number of patients died within the first twelve or twenty-four hours. Premonitory diarrhœa only preceded the real attack by a few hours, and if the patients did not succumb in the algid stage typhoid generally supervened and carried them off.

From the very commencement of the epidemic the Turkish Government took, entirely of its own accord, very praiseworthy measures to stem its progress and to mitigate the misery of the lower classes of the population. The Grand Vizier, Faud Pascha, called a general council of the members of the Quarantine Committee and the Professors of the Medical School, in which he presided, and which resolved that an extraordinary commission of public hygiene and salubrity should immediately be formed. This commission went to work at once; overcrowded dwellings were emptied, and part of the inmates ordered into tents and wooden barracks; the inhabitants were instructed by public placards how to protect themselves as far as possible from an attack; provisional cholera hospitals were erected, and the speedy removal of poor persons who were attacked in the streets was looked to. All this, of course, without any regard to religion or nationality. For carrying out these measures physicians were specially nominated for every quarter of the city; a number of assistants and a very liberal salary (6,000 piastres per month) were given them. Medicines were distributed gratuitously amongst poor patients, and food was given to the most needy of the inhabitants. The Turkish Government did, in fact, more in this emergency than any government ever did under similar circumstances, and that at a time when the public treasury is much straitened. A shocking contrast to the efforts of Faud Pascha and the Commission, which was presided over by the indefatigable Dr. Sawas, was the part played by the Primate of the Orthodox Church; for the Greek Patriarch "skedaddled" at the first outbreak of the epidemic to the Prince's Islands, surrounded himself with a strict cordon, and remained deaf to the general cry for help and comfort which arose from his suffering faithful flock.

In this epidemic the Medical staff of the metropolis has suffered considerably, for no less than twenty-seven physicians and Medical assistants died in the midst of their work.

The quarantine regulations as they are at present carried out, not only in Turkey, but also in the rest of Europe, have proved utterly powerless to check the progress of the epidemic; and yet strict measures of this kind ought to be able to protect us from it; for it is an established fact that where there are no cholera patients nor anything which has come in contact with them, there will be no cholera. Thus, for instance, Greece, where the strictest measures against its importation have been taken, still continues free from the disease, in spite of the considerable immigration into that country of fugitives from Turkey. In the South of Italy the authorities refuse admission to any persons coming from places infected by cholera. In Messina, the steamer coming from the East is greeted with cannon-shot if it approaches too close to the shore. Such proceedings appear to be entirely justifiable. It would, indeed, seem to be high time that the European governments should come to a concert as to decisive measures to be taken against the export and import of the epidemic. All the last visitations of the disease have proceeded from Mecca, from whence they were carried onwards by the returning pilgrims. Cholera places should therefore be surrounded with a strict cordon, and passports for abroad should be refused as long as cases still occur in such localities. The existing quarantine laws certainly require a sweeping alteration. To mention only one point, I may say that the rule which is now generally followed—viz., to subject ships coming from cholera places to a five days' observation—is arrant nonsense. I believe that on account of the advanced season of the year England will at present be spared the visit of this disagreeable stranger; but it would be culpable neglect if you did not do all in your power to prevent its rise amongst you next year.

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 4, 1865.

THE OPENING OF THE MEDICAL SCHOOLS.

The period has again arrived when the Medical schools throw open their portals for the reception of students, and the occasion is an interesting one both for those who have long ago completed their curriculum, and for those who are only just commencing it. To the former the reminiscences of the past will form agreeable subjects of meditation, to the latter the hopes of the future will dissipate anxiety and stimulate to exertion. It is so generally felt that the student should make a good start on this his first practical acquaintance with regular Medical teaching, that advice is always offered to the youthful aspirants by their seniors in the race, and the Medical Journals are very properly expected to offer their words of warning or encouragement at this appropriate season.

For many years the introductory addresses published in the Journals have continually lamented the want of State interference in Medical education, and their advice has been confined to exhortations to students to work out their own course, and to trust to individual diligence for eventual success in their career. The diversity in the methods of teaching, the inequality in the qualifications of students, and the various and often conflicting regulations of the examining boards, were deplored time after time as opposing unnecessary, but formidable obstacles to the acquisition of a uniform standard of knowledge or of professional position. The complaints thus expressed were by no means groundless, for under the system, or rather want of system to which we allude, the greatest anomalies were allowed to prevail, and both schools and examining bodies were found to take advantage of the then existing disorder in order to promote their own views and interests, and even to replenish their own coffers at the sacrifice of the dignity of the Profession which it was their duty to uphold. It will probably excite the wonder of posterity when history relates that, while Medicine and the collateral sciences were making rapid strides, candidates were admitted to diplomas in Medicine and Surgery on the most slender acquirements; and that at a period when general education was made more and more easy of attainment, candidates were actually permitted to enter the Profession without giving evidence of possessing the most rudimentary classical or mathematical knowledge.

Such a time has happily passed away, and however deficient the Medical Council may have been in many respects, it deserves at any rate the thanks of the Profession for inaugurating a new era in Medical education, and for opening out for the future a prospect of better and brighter days than we formerly could reasonably anticipate. It is now no longer necessary to exhort the student to acquire the rudiments of general education before he commences his Medical lectures and hospital practice, for the Medical Council now very properly enjoins upon him the necessity of passing an examination in Arts before registration can be effected, and in case any persons should still be ignorant of this regulation, we may state that it is now most stringently carried out in the case of all students entering the Profession. Those who fail to pass the examination in Arts, established by the different licensing or educational bodies, must postpone their entrance into the Profession until this ordeal has been surmounted; and the delay will be found beneficial rather than otherwise, by allowing some additional time for the improvement of the mind, and rendering it more fit for the reception of the facts and doctrines which make up the sum of a Medical curriculum.

The value of this regulation must at once be apparent, for it insures at least a certain amount of uniformity in the qualifications of students. In former days, the educated and the uneducated were associated promiscuously together, and the consequence was, either that the latter were compelled to scrape up the rudiments of general knowledge at the end of their term of pupilage, or by a bold leap they resorted to some of the less scrupulous examining bodies, and evaded the general education test altogether.

That these regulations have already diminished the number of Medical students throughout the United Kingdom is an established fact, and they will no doubt tend for many years to come to dissuade some aspirants who would otherwise have joined the professional ranks, but this result can hardly be regarded as unfortunate when we reflect upon the complaints which have so often been made of the overcrowding of our body, and when we witness the lamentable effects of that overcrowding in the want of union existing among us, and the undue competition which induces so many a man to endeavour to undersell or supplant his neighbour. When the number of the members of the Medical Profession is reduced, the services of each will become more valuable and will be more duly appreciated by the public, and there will consequently be the less necessity for resorting to those unworthy means which have been too often adopted for gaining public favour. By the influence, also, of a superior system of education, the members of the Profession will become more united to one another, and will be able to present a bold front against the encroachments of quackery, and against the perpetration of injustice on the part of the public.

The student having effected his registration and selected his school, must at once enter upon the beaten track, and commence with the study of anatomy and chemistry. He must diligently attend the lectures on those subjects, take notes of the prominent topics introduced by the professor, and when he reaches home, must copy out his notes and amplify them, if necessary, by reference to good text-books. He must also be a constant attendant in the dissecting-room, and as opportunity offers, he must make himself practically and thoroughly acquainted with the structure of the human body by means of his own scalpel and the help of a good manual, and when he is not dissecting himself, he should superintend or watch the dissections of others. The same facilities which are pro-

sented for his practical pursuit of anatomy, will be offered to him afterwards, in the case of chemistry, in the laboratory, where he will be able to realize with his own hands the lessons he has heard in the chemical lecture-room. By personal manipulation of weights, retorts, crucibles, and test-tubes, he will acquire accuracy of thought, and skill in practical operations, and the experience thus gained will be of inestimable service in after-life when he reasons upon the phenomena of disease or devises methods for its alleviation or cure.

It is so important for the student to acquire during his first season an accurate knowledge of anatomy and of the principal laws and doctrines of chemistry that all other subjects should be made subordinate, even the attendance upon the sick and the assistance at surgical operations. These duties cannot be efficiently performed until the student has made himself acquainted with healthy anatomical structures, with physiological laws, and with chemical changes and decompositions, and therefore if during the first session, choice must be made between the operating-theatre and the dissecting-room, the preference should be given to the latter. As opportunity offers, however, the practice of Medicine and Surgery should be attended in the intervals between the lectures and the dissections, but the full attention of the student to the details of practice in the hospital should in general be postponed until the second winter session.

MEDICAL REMUNERATION.—IRVINE *v.* WILSON.

The subject of Medical remuneration is one which necessarily interests very deeply the members of our Profession, and therefore a recent case which has occurred at Liverpool is deserving of comment. It appears that this was a trial for the recovery of Medical fees, set down for hearing at the Assizes, but referred to arbitration; and although the proceedings were consequently private, a report of them has appeared in a contemporary journal. The general features of the transaction may be gathered from the subjoined abstract, taken from the letter of a special correspondent of the 'British Medical Journal,' and which appears to us to put the matter in a very fair and impartial light. Our own impression is, that under all the circumstances, the charges made by the plaintiff were a *leetle* too high, and that the defendants were not altogether without justification in resisting the payment. But some of the evidence given as to the fees demanded by surgeons was so extraordinary and the amounts described were so extremely different, that we cannot wonder at the present unsatisfactory state of the relations existing between practitioner and patient. One of the witnesses (Dr. R. Robertson) is reported to have said that Mr. Spence, of Edinburgh, charges two guineas for passing a catheter, but that he usually receives five, and that Mr. Fergusson, of London, might charge ten or twenty guineas for performing the same service. This may be true, but if so, the facts come upon ourselves with the air of novelty. On the other hand two Liverpool practitioners, Dr. Whittle and Mr. Wiglesworth, both declared that two shillings and sixpence! was the usual fee for passing the catheter, and that three shillings and sixpence would be "ample remuneration." This rate of charges also comes upon us by surprise, and we can only suppose, in explanation, that the scale of fees in Liverpool is excessively low, and that in Edinburgh and London it is extravagantly high. The following is the abstract to which we have alluded:—

A young practitioner of acknowledged talent and respectability, who has lately commenced a general practice near Liverpool, was called on to attend a gentleman whose case appears to have been somewhat complicated. Being a highly nervous and anxious subject, he made large demands upon the time and patience, as well as the surgical skill, of his Medical attendant, who was obliged to pay many daily visits, at all hours, and frequently for the purpose of using the catheter or bougie. The attendance extended over a period of eight months. The patient ultimately died; and a bill, amounting to 250*l.*, was sent in by the surgeon alluded to, and which the representatives of the deceased gentlemen considered was an overcharge, and refused to pay. Hence arose the notice of action, and subsequent reference to a barrister as arbitrator; who, assisted by two Medical practitioners as assessors, reduced the plaintiff's claim of 250*l.* to 190*l.*, and settled the case by an award of the last named sum. There is a very general opinion amongst the Profession here that the original demand was difficult to reconcile with the ordinary rates of remuneration obtained or expected by practitioners in this or in any other part of the country. The visits, however numerous, in the same day, were charged five shillings each; which, considering that the patient's residence was close to the surgeon's house, and that as many as ten visits were paid in one day, might be considered a full, but hardly an unfair charge. But, beyond the fee of five shillings for the visit, an additional charge of ten shillings was frequently made for passing a bougie or catheter, even although many of the visits were required solely for the purpose of performing that operation. These and other items appear to have been regarded by the referees to be fairly open to question; and there is reason to believe that their view of the matter is one which would have been pretty generally endorsed by the profession at large. As a general rule, none are so inadequately remunerated for their services as Medical men; but there must, of course, be a limit beyond which no prudent man will venture, lest he subject himself to a suspicion of extortion, with the humiliating alternative of having to accept, as in this case, much less than the value he places on his own services. A redeeming feature in this unpleasant business, and one which does much credit to the good sense of the party chiefly concerned, is the withdrawal of the case from publicity by consenting to the decision of a private referee, thus avoiding a public scandal injurious to the interests of the profession, and anything but conducive to his own peace of mind.

REVIEW OF BOOKS.

Winter in the South of Europe; or Mentone, The Riviera, Corsica, Sicily, and Biarritz, as Winter Climates. By J. Henry Bennet, M.D. Third Edition. Pp. 442. London: Churchill and Sons. 1865.

San Remo as a Winter Residence. By an Invalid. 1862—1865. Pp. 128. London: Churchill and Sons. 1865.

The Climate of San Remo as adapted to Invalids. By Henry Daubeny, M.D., M.R.C.S. Pp. 39. London: Longman and Co. 1865.

Those who have had the good fortune to travel along what is called the Cornice Road, leading from Nice to Genoa, will not readily forget the manifold beauties of that magnificent pass, sometimes ascending the heights of the Mari-

time Alps, sometimes skirting the sea-shore, and affording, along nearly its whole extent, the sublime prospects of the mountain scenery on the one hand and of the blue expanse of the Mediterranean on the other. In the favoured region thus traversed, Nature is invested with all her charms, and her face is seldom disfigured by those storms, winds, and rains, which not only depress the spirits but impair the health of mankind in the more northerly climates of Europe. The summer, indeed, although characterised by a cloudless sky, is too hot for human comfort, and is injurious even to the pulmonary invalid; but, on the other hand, the winters are rendered mild by the very circumstances that make the summers oppressive; the north winds are shut out by the mountain ridges which skirt the shore, and the towns are exposed only, or chiefly, to the warm breezes of the south. During the winter months, when our own nebulous atmosphere is loaded with heavy leaden-coloured clouds, and when we all, well or ill, are glad to take refuge by the side of our coal fires, the resident in the Italian Riviera is basking beneath the sun, shining at Christmas with undiminished brightness, though with mitigated heat, and rendering the resort to artificial warmth almost entirely superfluous. Among the bounties of the Maritime Alps, coals are deficient, but their want is scarcely felt, as the cooking is performed by means of charcoal, and the wood of the district is amply sufficient to provide fuel on the few occasions when the rain or the cold demands the use of fires in the sitting-rooms.

The vegetation of this beautiful region is in accordance with the characters of the soil and the climate. From the long absence of rain, and the arid nature of the earth, the verdure of meadows is indeed wanting, and the varying colours of the foliage of deciduous-leaved trees are somewhat missed; but, on the other hand, the profusion of evergreens more than atones for this deficiency, for the vegetation is thus continuously present during the winter as well as the summer months, and owing to the mildness of the climate the spring flowers make their appearance long before the winter has passed away, or, indeed, before it can be said to have well begun, while many of the forms of vegetation familiar to our own eyes appear among the rocks and the groves of the Riviera during the comparatively cool months of the winter and the spring. The splendour of an almost tropical flora distinguishes the summer, when the myrtles scent the air with their fragrance, the fig-trees ripen their welcome fruit, and the prickly pears hang out their succulent spine-covered leaves and berries from the crevices of the limestone rock. Grapes are cultivated in abundance, or rather were so, before the oïdium attacked the vines; lemons and oranges with their golden fruits, staple articles of commerce in these regions, constitute entire groves; and forests of olive trees, valuable for their oil, with their spreading branches and umbrageous leaves, afford cool retreats and grateful shades from the heat or the brightness of the sun.

Dr. Henry Bennet, having in former years been struck with the beauties of this part of the Italian coast, has lately, as is well known to the Profession, adopted it as his dwelling during the winter months, in consequence of an attack of illness which rendered his continuous residence in England unadvisable. He has, therefore, on his own account, studied the peculiarities of the climate in reference to the restoration of health, and he has in several editions of the present work made known his experience to the Profession and the public. The work, however, as first published in 1861, was a mere essay on the winter climate and vegetation of the country around Mentone, but it has now been expanded into a larger volume comprising a description of the meteorology and winter climate of the northern shores of the Mediterranean in general, and, in addition, it contains an account of various excursions in search of health quarters, for winter and summer, in Italy, Corsica, Sicily, the Italian lakes, and Biarritz.

On the old principle, "*on revient toujours à ses premiers amours*," Dr. Bennet, after all his wanderings in search of health resorts, gives the preference to Mentone, where he has taken up his own winter quarters, and where, in fact, he habitually resides, dividing his time between this Franco-Italian town and London. It is probably well known that Mentone is one of the two or three towns which, with a small strip of country, constitute the principality of Monaco, until lately governed by an independent and sovereign prince, then converted into a small republic, and finally annexed (as it appears, against the wishes of the inhabitants) to the French empire, to which it now belongs. The peculiarities of the climate are thus summed up by Dr. Bennet. "The characteristics of the climate of Mentone, and of the Riviera in general, as evidenced during the six winters I have spent there, are: the absence of frost; the prevalence of northerly winds; the complete absence of fogs; the paucity of rainy days; the clearness of the sky; the general heat and brilliancy of the sun; a rather cool or chilly night temperature; and a bracing coolness of the atmosphere throughout the winter, out of the sun's rays. Even when the sun is obscured by clouds and rain-falls, as the wind is then generally from the south-west or the south-east, it is not cold at any period of the winter. On the rare occasions, however, when it rains, with the wind from a northern quarter, there may be as miserable and chilly a state of things as in a drizzling November day in England. As rain only falls on a small number of days, and then often not during the whole day, and as the other days are uniformly bright, clear and sunshiny—for five days out of six throughout the winter—exercise in the open air can be prudently taken from nine until three, four, or five p.m., according to the season, with both pleasure and benefit." Pp. 80-81.

Although written by a physician, and with the prominent object of describing different localities in their relation to human health, Dr. Bennet's book is replete with varied information upon a great multitude of topics, and his pages will be read with interest by all general readers. His own tastes, pursuits, and studies, are evidently such as to enable him to appreciate keenly the beauties of Nature, the triumphs of art, and the lessons of history; and we therefore find him equally at home in describing the scenery of the Italian coast, or the ruins of Syracuse, or the career of the first Napoleon. With such a guide we may be amused and instructed by the description of the physical geography and botany of Corsica, with its reminiscences of the Consulate and the Empire; of Sicily, with its fertile fields, its world-famed volcano, its ancient and modern cities, its ever-changing political history; or of Biarritz, with its new fledged popularity and its crowds of bathers and promenaders. All these scenes are brought before us in a familiar and easy style and without any pretentious display of learning, and, indeed, it is evident, from certain unimportant inaccuracies, that most of the remarks have been written *currente calamo*, and without a recourse to books; but, nevertheless, as we have stated, the descriptions and remarks are vivid and truthful and convey the impression that they emanate from a highly cultivated and observant mind.

The second book named at the head of the present article, entitled "San Remo as a Winter Residence," is written by an invalid who is not a member of our Profession, nor even a scientific man, but who desires to make known to the world the advantages to be derived, in certain cases of illness, from a residence in the town in question. San Remo, like Mentone, is on the Riviera, or Italian undercliff, and the two towns are situated at only a few miles' distance from each other; but San Remo is still Italian, the boundaries of the French empire not extending at present beyond Roccabruna. The invalid whose name is Mr. Aspinall, states that he has not found any other climate from which he has derived so much benefit as that of San Remo, although he has passed one winter at Madeira, another in Egypt, and shorter periods in Rome, Naples, and Sorrento. He tried Nice, but found the climate very treacherous, the bright, hot sunshine being counteracted by bitterly cold winds sweeping through the gorges from the snowy mountains; and he disapproves of Mentone, partly for the same reason, and partly because it is sometimes too warm, and invalids find it too close and relaxing. San Remo, according to him, combines, in a modified degree, the invigorating qualities of Nice with the warmth of Mentone but without its closeness, and is therefore adapted for diseases of the chest especially if the dige-

tive organs are impaired. Although this little work aims at no scientific character, it is amusing and instructive, and will be welcome especially to those who are thinking of visiting the Riviera either for health or relaxation.

Of the brochure entitled "The Climate of San Remo as adapted to Invalids," by Dr. Henry Daubeny, we might speak favourably, had it not been shown, upon what appears to be sufficient evidence, that it is little else than a plagiarism from another pamphlet on the same subject, and which we noticed a few weeks since.

"CYCLOPS'" TWENTY-FIRST LETTER ON PHYSIOLOGY.

To Vigilans.

Sir,—What do we know of the colon, called *par excellence* the large intestine? If we regarded it from the point of view of the general practice of Medicine, or the ideas prevalent on its treatment by the public themselves, we should say that it was an organ simply provided by Nature to receive that portion of the ingesta which, being of a solid consistence, could not be absorbed into the system, and therefore placed out of the way in this receptacle; Nature dictating the removal of it. Now, this law has been considered by the Faculty very imperatively, and that the contents of every man, woman, and child's colon should be emptied at least once in every twenty-four hours. The very idea of the contents of the colon being useful in the body seems never for a moment to have been thought of. Indeed, so far from this has the imagination strayed, that the fæces have even been considered such poisonous elements in the system that it is believed to be the bounden duty of every man who is considered at all eligible to practise his profession that he should at all times attend to this viscus first. He therefore has always been considered the wisest and best practitioner who acted on the plan of "clearing the ports," "attending to the primæ viæ," "purging the liver and bowels well," as the very first step in all cases in which he was called in, and then seeing where disease lay lurking in the body. Having done this essential and necessary act, and seeing that no poisonous fæces or substantial elements existed in any part of the alimentary canal, the coast was said to be clear; for, to use one of their similies, if this was not done, "we should be putting a clean carpet on a dirty room." Nothing could resist such an appeal to the apparent truth so patent to everybody. In this everybody seems to agree, and in fact the majority of the public hardly imagine that any good is done by medicine unless it acts upon the bowels. Therefore medicine has more or less been directed to this great end. At certain times in every year there is always some alarm about cholera; the daily journals, the Medical Journals, the Privy Council and Ministers, the Boards of Health and Sewage, all agree that when the fear prevails of this dreaded disease that it is incumbent on all to set their houses and premises in order, to get good air, ventilation, and drainage, and, in fact, disseminate the fear they feel themselves amongst all classes; that unless some outward and visible thing is done this plague will be amongst them; just as nurses alarm naughty children with the cry of "Old Bogy's coming," and other fictions as a means to an end. What, then, are all so much afraid of? What is this terrible thing that seems to make men's hearts sink within them? Is it relaxed bowels? Not at all! Is it diarrhœa? Oh, no! It is one step further than these: it is an aggravated relaxed bowels added to aggravated diarrhœa from some inexplicable cause. But why be so frightened about this? One would have supposed that the English community, at least were accustomed to this, because from time immemorial, not only the Faculty, but they themselves, have been for ever making an artificial cholera in everybody by the free use of aperient and laxative medicines. Surely after all these years when we have been so accustomed to these purges on every occasion, and well know that if we did not do this ourselves, directly we sent for a doctor that he would; surely we ought not to be so frightened at a spontaneous act, even when a little aggravated, when we are always doing it ourselves in some degree. We ought at all events to be so used to it that we might rather say, "Oh! for a good diarrhœa! Oh! for a good cholera! to clear us out well, and save the taking of filthy and nauseous drugs; clearing the house of all dreadful and offensive matter; making all its rooms clean and sweet in order that we may lay down this new carpet, and fresh paper the walls, paint, whitewash, and generally amend the great house of life, so that, as our own drastics are used on the one hand artificially upon the received authority and dogmas of the Faculty as a body, we ought to feel indebted to Nature, who, through some of her inscrutable laws, sets up the same modus medendi, and sweeps everything clean out of us. But if the Faculty have done this for many centuries, and considered it right by every book and dogma, then I begin to consider that Nature herself has been very wrong; in fact, that she has been nothing but a bungler, and made a most unwise arrangement of the colon. When she made the first receptacle for fæces, the cæcum, so near the anus, why not have made a short cut thereto at once, and as fast as feculent matter was deposited to have got rid of it? She could have made it under the influence of our will the same as she has done the bladder. If the fæces are poisonous substances, which in truth to say they are, why did she adopt the plan she has, and make a gut, a sink, and a cesspool to go all round the abdomen at the risk of poisoning the very body she has taken so much pains to make so beautiful? It is very evident, then, that either man is right and Nature wrong, or Nature is right and man exceedingly unwise in not finding out what her intentions were, and after all these years of physicking and purging, how culpable as well as ignorant. Having said this much, and agreeing entirely with Nature, I have something to say of her wisdom and her great bounty in all she has done. Anatomists and physiologists have really done their duty in many respects. They have given a most fair and just account of what they have discovered, but the fault lies deeper than we are aware of. The anatomists have shown the shape, position, and character of this intestine; that it commences at the cæcum, and whenever anything gets there, certain valves close it, so that there is no retracing of its steps; it is for ever shut out of that part of the body from whence it came. Directly it gets there, if the colon could speak, and why not? Did not Rousseau, Gay, Æsop, and other writers make birds, animals, and reptiles speak? Why should I not give a tongue and voice to the colon and the fæces? Well, then, the cæcum says, "You have been in a desperate hurry to get here;" "Yes, I have," says the fæces, "but I am very different to what I was when I first went into the mouth; I am somehow mixed up with everything I came into contact with; the usage I got in the stomach was something fearful: my character was literally destroyed, and I was mashed up and sent about my business as quickly as possible; then I was seized by another stomach and all the sourness taken out of me, while all my oil and grease were saponified and then mixed with all the rest. I was detained a little there, but soon expelled; then I got squeezed and pressed through a long tunnel with no end of turnings, and with all the juice taken out of me, I was hurried on here, and so, I suppose, I must be served the same way now." "Not at all," says the cæcum; "you have been hitherto in one confused state of bustle: policemen everywhere to order you to move on; but you will find policemen here to arrest you at every step—indeed, you can't move of yourself. Do you see that hill before you?" "Yes," says the fæces, "how am I to get up that?" "You will have to wait until you are pushed up by another, and the next by another, and so on, so that there is now an impediment offered in every way to your progress." "But," says the fæces, "I am become a poisonous mass, once so sweet, and savoury, and appetising; I am, by dint of the processes I have gone through, become so perfectly disgusting that my very aroma is positively unbearable, and my exhalations are more poisonous than my whole bulk; so much so that I should have thought you would have been glad to get rid of me as quickly as possible, instead of detaining me." "There is a great difference of opinion on this subject amongst the Faculty," replies the cæcum; "the majority have always

thought as you do, and that the great end of medication seems to have been directed to your expulsion."

Now, it is a curious fact that in every generation this subject crops up, and demands a thought to be bestowed upon it. Dr. Bailey, of "Ulceration of the Stomach" notoriety, was averse to giving aperients in fevers. Dr. Paris, in his pharmacologia, says:—"Did it never occur to the pathologist that Nature may upon some occasions wisely retard that operation which she is so anxious to provoke?" In fact, many physicians, relying on their *experience* as they get older, have abstained, to a great extent, from giving cathartics. There have also been sound-thinking general practitioners who have also come to the same conclusions. But ask them, as I have many, their reasons, and you will probably get the same answer as I have—namely, "My experience pointed it out to me; I have no philosophy." Here is the old story, *experientia docet*. In fact, they have all only been empirically correct; so that this treatment having been adopted more or less almost everywhere by all classes of practitioners in every generation, shows that it is nothing new, but yet having a great deal in it. If at any time certain of the Faculty have been bold enough to record their opinions in some Medical Journal by way of ventilating the subject, it has probably been coupled with the treatment of some case wherein they wished to enlighten their professional brethren.

Thus, then, it may be said to have simply ended there, for ten to one if any of their readers would meet with a similar case to try the new idea upon. Precisely as we see now-a-days, cases recorded in either private or hospital practice, or read before some physical society, of some vagaries of the secretions producing certain curious symptoms or diseases with the author's treatment and its results. Well, what is learnt by them? There is never any philosophy given, and no point of physiology developed, and when they have been duly read or listened to, what does anyone know about it, and who is the wiser? They have carried no conviction, and no new fact has been impressed upon the mind. This shows the importance of some philosophy being attached to all these proceedings for any good or any truth to be substantiated or engrafted on the mind. If we take the observations of such men as Dr. Bailey, or Dr. Paris on the subject, we find them only empirics in the matter; they have left only their own opinions, the same as other men have done, with no philosophy at all for what they did. No doubt all these men believed they acted *sua sponte* on all such occasions, and each that it was his own peculiar idea, because it was the exception to a very general rule. "As from the shaft no trace is found; no scar the sky retains; no furrow from the keel;" so likewise does all this cropping up of Medical treatment by experience without philosophy or physiology die away and leave no trace behind, no impression and no beacon for others to steer by.

For my own part, I look in vain as every hospital session comes round, for some one to step out of the dull tame routine and groove in which the practice of medicine travels and seems destined to travel, without thought beyond the current belief of the day, or any genius for the future.

I see, by the way, that Dr. Radcliffe has ventilated the subject of aperients at the British Association, pretty similarly to many who have gone before him. As his ideas, therefore, are the latest, and may no doubt be considered by many, a fair exposition of present views, it will be worth while to see if they hold water and bear the test of criticism, in order that he may get all he deserves for bringing them forward. I will endeavour to do this in my next letter.

I am, &c., CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on the 21st inst.:—Thos. Edw. Gaggs Bywaters, Knottingley, Yorkshire; Richard Samuel Purnell Griffiths, Cheltenham; James William Horsfield, Sunderland; John Edward Tilton, Stonehouse, Gloucester; Robert Wood, Uttoxeter, Staffordshire.

THE CATTLE DISEASE.

A disease bearing the appearance of being identical with the cattle plague, has been ravaging a large flock of sheep in Norfolk belonging to Mr. R. F. H. Harvey, M.P. Upon this estate the disease was first introduced by some cattle, and the sheep had been pastured with some of these very cattle. We have, therefore, at least as strong evidence as can be expected, not only that the disease of the cattle has broken out among the sheep, but that it is equally liable to be communicated from one class of animals to another. On his estate at Croon Point, near Norwich, Mr. Harvey has also lost ninety beasts, valued at 5*l.* each, and some forty calves, valued at 2*l.* 10s. each.

The Committee of Foreign Importers of Cattle have fully investigated the history of the Revel cargo, which was alleged to have introduced the disease into this country, and have furnished documentary evidence which places the matter in a very satisfactory light. The cargo were not diseased, and the origin of the disease must, therefore, be sought for elsewhere.

The Privy Council have issued new and extended orders in relation to the disease, to meet the exigencies of the case. The word "animal" shall mean any cow, heifer, bull, bullock, ox, calf, sheep, lamb, goat, or swine; and the word "inspector" shall include any inspector appointed under the orders, with power to examine and inspect, wherever and whenever he may deem it necessary, any animal within his district.

Dr. Fürstemburg, Professor in the Royal Academy of Eldena, insists through the 'Times,' that the disease "is Russian, and only Russian." "We well know," he says, "that it is an impossibility that it should develop spontaneously among the herds of Western and Central Europe, and the plan we followed most effectually in putting a stop to this malady is based on a knowledge of the fact which seems to have been disputed in England. All that we have heard in times past has been confirmed by observations during the present outbreak. The disease was brought from Russia. It broke out where contagious disorders have always been rife, owing to daily or weekly purchases, viz., in the London dairies. It was kept up by markets, and taken to Holland on the 7th July by Dutch cattle which had stood the London market. From Holland it passed to Belgium, and from the cattle market at Malines it was communicated to stock in France, where, thanks to prudent measures, it has failed to gain a hold." As regards our negligence in relation to the disease, the doctor says:—"The Dutch skin the cattle, and sometimes throw the carcases into the canal, not to be troubled in burying them. The English are not less reckless. There are knackers close to the high road to the Metropolitan Cattle Market, to which dead animals are brought in an open cart emitting discharges in all directions. I have dissected one within a few yards of such a road, and what has astonished me more than all was, the animals had died at the Royal Veterinary College and been removed to the horse slaughterer without being opened, on small carts which could not adequately contain them."

"S. G. O." the well-known correspondent of the 'Times' remarks upon the slaughter mania of semi-diseased cattle which so widely prevails:—"It strikes me as madness to destroy every beast affected with the epizoic. I do not believe you lessen the infection on the spot. I cannot but hope that a downpour of rain, a gale or two of strong wind, must come before long, and I firmly believe that this would do more good than anything we can ourselves do. The public markets will be the great agents for the spread of the disease. Closely packed for hours without food in a railway truck, exposed to the sun's rays, then driven into a steaming crowd of tired beasts, standing on excrement poured forth in excess from distress and heat, I can conceive no better way of inviting the disease to break out in any beast that may from any cause have absorbed the virus."

GENERAL CORRESPONDENCE.

To the Editor of the Medical Circular.

Sir,—Having given a brief historical sketch of cholera as appeared in this country in the years 1831 and 1832, I n induced to lay before your readers a "*résumé*" of a mmunication in respect to my then more matured inions and views of the disease, as it appeared in the years 48 and 1849, a reprint of which, I doubt not, will tend y a careful perusal) to allay unnecessary fears and appre-nsions now existing in the minds of the community.

I am, &c., Thomas R. Torbock, M.D.

Darlington, September 28th, 1865.

'I take leave, respectfully, to trespass on the columns your valuable journal, in consequence of certain state-nts having been rendered by a distinguised physician tive to the sanatory state of Monkwearmouth, and its inity, in connection with the present epidemic (cholera), ich has now been prevailing for several weeks past—re especially in the district in which this gentleman, others mentioned in the columns of the 'Sunderland rald' of last week, and who, moreover, are said to have *special* charge of the said district. In justice to myself, l also to the community, I therefore deem it needful to e the whole facts, not having hitherto reported *a le case of Cholera*, either to Government officials or ers. I would not, for one moment, call in question the acity of the statement thus rendered :—viz., there having n only *thirty-two cases, and seven deaths.* This may, and elieve does, apply to the number of cases had under tment; but the mortality, according to the registration leaths from cholera, much exceeds the number stated. ave, therefore, endeavoured to collect true information this point, which will be seen by the accompanying istics. The returns will thus show how far I have been essful in the treatment of this disease. For the conso-on of such as feel dread even at the very name of this htful scourge of human nature, I am emboldened to e from past, but more especially from present treatment, t there is no disease so much under control during its *t* and *second* stages; thus preventing the 'rapid type.' great misfortune has been, and indeed is still, by the munity being led to imagine *epidemic diarrhœa* (bowel plaint) at the present time, and cholera are not one and same disease.

This was a misfortune here in 1831, when Drs. David y, Daun, and Gibson, the Government officials reported; who in the reports caused this distinction, the conse-ice of which induced the community to neglect the *rhœa*—very many cases of which ran into the 'rapid ' My opinions were more especially confirmed in the 1832, at Hartlepool, when my colleagues as well as lf, found the whole of the inhabitants, more or less, ubjects of *diarrhœa*, many of whom, previous to our al, had assumed the rapid type and had terminated y. It would be impolitic to enter at this present into ircumstances and treatment during the few days we Medical charge of that place. I am, therefore, proud y that my views are now confirmed by one high in rity at the present day, that 'Diarrhœa and cholera, logically, are one and the same disease,'—the former ituting the *infant stage*, the latter the grand finale—*reaking up of life*—'the struggle between the pro-exhaustion, caused by the disease, and the powers of ystem.' Let the community, therefore, be disarmed is fallacy; when I doubt not they will be led to seek al assistance *early;* and thus by proper remedial s, saved from its more direful results—the 'rapid and death. My views are more particularly con-in the outbreak of the disease at the Infant Asylum, oting; it is said some of them were attacked with *œa*—several of the cases *assumed* the appearance of ic Cholera'—and death followed. Now, had the *otion* applied to *all the cases*, in all probability, many n might have been saved from the more fatal stage of the disease. There is no doubt it was nothing less than *cholera*, from the earliest stage to the closing scenes of life.

"In conclusion, I beg to remark that a question now arises :—How is it, viewing the present returns, and the number of recoveries in relation to the deaths, and more especially, if we place in juxtaposition the returns from the city of Glasgow, where the mortality has been very great—the total numbers reported from the 11th of November being—cases, 2,954; deaths, 1,206; recoveries, 694. Truly a frightful state of things. This, in some measure, may be readily accounted for, from that want of confidence in the medical attendants, whom the afflicted imagine are deputed to get rid of them by poison, and, in consequence, refuse their assistance; and who will not, owing to the like impressions, go into hospitals provided for them. This distinctly shows how necessary it is that the medical practitioner should have the confidence of the sufferer, otherwise it is sure to militate against him. To return to former observations, and more particularly to corroborate my opinion as to treatment in the way of *prevention*, Mr. Grainger (one of the brightest ornaments of our profession, and who is one of the commissioners appointed by Government), in a lecture recently delivered at St. Thomas's Hospital, says—'I most earnestly hope, then, that the attention of pathologists will be directed to the great question of *prevention*, rather than of *cure*, and particularly to the enlightenment of the public mind upon the subject.' The old adage 'Prevention is better than cure,' is no doubt the great desideratum in all matters, professional or otherwise; but the expression has great latitude when we consider its application to disease. The mariner upon the troubled ocean cannot control the winds and the waves, nor prevent the approach of the impending storm; but if skilful in his avocations, and judging from circumstances around him, he will judiciously guard the ship from its influence, and though she may even suffer in the conflict, the trusty barque and crew are in all probability saved. Alike, the puny arm of man cannot control the aërial visitant—'the pestilence which walketh in darkness'—no doubt at this moment pervading the continent of Europe; neither can he subdue the great and vast important changes in Nature's operations, alike unseen, but felt by his frail tenement; but the wisdom that directs may so far enable him to adopt means which are best calculated to arrest the direful ravages of its onward course—which proving beneficial may thus save him from the destruction of the pestilential storm. Thus far, if my humble endeavours have been crowned with success, they are deserving of the term '*prevention,*' and the grand desideratum is accomplished.

"I am, &c.,

"Thomas. R. Torbock, M.D.

"14 Lambton street, Sunderland,

"January 15, 1849."

THE SANITARY STATE OF ST. GEORGE'S, SOUTHWARK.

On Friday evening there was a full attendance of the vestry of St. George's, Southwark, on its re-assembling after the holydays, in anticipation of some answer being given to the statements which have appeared relative to the wofully neglected sanitary condition of the district under the vestry's jurisdiction. The Rev. Dr. Hugh Allen, the rector, presided. The early part of the sitting was taken up with parish details; but these passed almost without notice, for the vestrymen were occupied in scanning an illustrated newspaper, in which appeared several cuts of wretched dwelling-places in the parish, and one, depicting a nude child in a miserable court of the parish appeared to receive their deep attention. The subject matter was brought before the assemblage by the Medical Officer of Health, Dr. H. Bateson, who read the following report :—

During the last five weeks ending the 16th of September 125 deaths have been recorded, giving an average of twenty-five per week; only one out of these was referred to fever. This epidemic is now apparently dying out, to be succeeded,

however, I have no doubt, by some other, for generally one is present preying upon society. Such, experience tells us, has been the case in the past, and such will be the case in years that are to come. There is one fact it seems to me we are apt to overlook, and which is that moral causes are as powerful in the production of disease as physical causes. Present circumstances will compel me again to bring before your attention the subject of fever. I fear that I shall weary you in doing this, as I have frequently brought it before you in my previous reports; no very serious attention has been paid to them, otherwise much of the present excitement might have been stayed at its commencement, or, indeed, might never have commenced. I have always been anxious to place before you an exact account of the health of the parish. I have as far as possible avoided exaggeration, neither making it out to be cleanlier, nor healthier, nor more salubrious than any other district is; nor have I represented it as the foulest, filthiest, and most neglected; in fact, I have not represented it in the form of a hideous caricature, which alone could excite in your minds the wonder how any one should dare to live within the precincts of St. George the Martyr, unless, indeed, he desired to emulate the self-sacrifice of him whose name it bears. When fever, and I may say any other disease has been rife among us, it has been invariably represented by certain numbers as if it were confined to this district alone, and hence was readily drawn the inference of our wretched condition. Such a proceeding is simply monstrous, and indicates a settled and determined purpose to degrade the parish and those into whose care the parishioners have placed it. How perverted must be that reasoning which ends in the conclusion that the fittest and most approved way of advancing the sanitary interests of the parish is to impugn the motives, deny the efforts, and rouse the indignation of society, by every means, against a body of men who are willingly and voluntarily sacrificing their time and talents for its welfare. "Power dwells with cheerfulness, and hope puts us in a working mood, while despair is no muse, and untunes the active powers." Such a line of conduct tends simply to crush all hope and engender mere despair. I will now place side by side the mortality which has happened in London from fever, for every quarter, from and including the year 1861 until now, with that of this district during the same period. I must tell you that London is divided by the Registrar-General into 36 districts. In the successive quarters of the year 1861 the deaths in London from fever were as follow—354, 347, 429, and 624, making a total of 1,754; in the district of St. George-the-Martyr, 10, 16, 2, 5, making a total of 33. In 1862, following the same order—991, 1,015, 833, and 796, making 3,635; in St. George-the-Martyr, 31, 48, 19, and 9—107. In London, 1863, 735, 624, 652, and 881—2,892; in St. George-the-Martyr, 12, 19, 25, 33—89. In London, 1864, 862, 783, 980, and 1,064—3,689; in St. George-the-Martyr, 36, 37, 36, 26—135. In London, 1865, 936, and 700—1,636; in St. George-the-Martyr, 29 and 11—40. Fever has been raging over all the land, in town and country, since the year 1861, and to a degree which has never before come within our knowledge. In some of the provincial towns it has been so severe that the Privy Council has sent commissioners to inquire into its cause and extent. Numbers of Medical men have been stricken to death in these places while in the performance of their arduous duties. Nothing of this kind has happened here; yet notice is vehemently called to this locality as if fever had existed to an extent and degree of mortality unequalled elsewhere. This is purely fallacious, and all that is unequalled is the conduct of the alarmists. We should be led to infer that, after all that has been done in the way of sanitary improvement by this vestry, we are in a worse plight than before it began its labour, and that we are less prepared to face epidemics than formerly. It requires the mere gift of making a noise to point out faults, while it requires wisdom to remedy them. The former we have had to satiety, now let us have the latter. Take St. George's, New Town, as an example of one of the worst parts of our district, and what do we find there? There are two evils which at once claim our attention—viz., overcrowding and want, and want, too, keeping the system in a diseased state—a corrupt state, precisely fitted for the reception of, and for the fostering to maturity any infection that may be abroad. Then there are the houses, totally unsuitable for the subletting, even in floors, whereas every room is let off, and to families. These evils, said in so few words, circle out so widely and entail so vast amount of wretchedness and misery that I cannot follow nor reveal them; besides, the people themselves have fallen into a degenerate state, and from causes hitherto which neither they or others have the power to hinder. They have not only no heed, but an utter contempt for cleanliness and what we should esteem comfort. The sins of the fathers have fallen upon the children; from diseased bodies and debased minds follow generation after generation. To destroy all these sources of harm and disease, what a work to be done, what a change to be wrought, what a time to be required. Houses must be built for the purpose of subletting and with every proper appliance, it matters not how plainly. Our streets are full of such as never can be improved. Then there is need of cheap and wholesome food; nothing will supply the want of this. A family well fed, with the dirtiest surroundings, will pass far more safely through an epidemic than will the most cleanly family with empty stomachs and pinched faces. I consider suitable habitations of the greatest importance, and not less so a sufficient supply of proper food. Sometime ago I showed you how closely mortality and density of population were connected. The Registrar-General has just published a supplement to the 25th Annual Report in which this is further illustrated. Fifteen examples are given. I will select a few. No. 1 district has 18 persons to the square mile and a mortality of 14 annual deaths to 1,000 living. No. 129 district has 201 persons to the square mile and a mortality of 20 annual deaths to the 1,000 living. No. 26 district has 1,909 persons to the square mile and a mortality of 24 annual deaths to 1,000 living. No 14 district 3,142 persons to the square mile, and a mortality of 26 annual deaths to 1,000 living; and No. 11 district 3,830 persons to the square mile, and a mortality of 28 to 33 annual deaths to 1,000 living. Now this district has the astounding proportional population of 125,980 persons to the square mile, and only the annual mortality of 29 to the 1,000 living, and while each person should not enjoy less for the barest support of health than 48 square yards in this district he has but 24½, and the population is still increasing, while the means of housing are decreasing. We cannot extend our borders, for we are hemmed in on every side, and we have no open space but that on which Bethlehem Hospital stands. Now, would it not have shown a greater earnestness and sincerity of purpose for the benefit of the poor, if some judicious measures had been proposed whereby this thronging here of humanity might be lessened rather than have spent effort and time in abusing the vestry for not having done that which yet is utterly impossible to be done? It is very easy to represent a district as a catalogue of horrors, and to say that ever since the resignation of Mr. Bendle it has been swept continuously through and through with epidemics—statements which I deliberately affirm are not true, and alone disgraceful to those who uttered them, and not to those against whom they are uttered; and I deliberately bear witness to the falseness of the accusation that the vestry is opposed or indifferent to sanitary progress. I have now had six years' experience, and I declare to the contrary. I have been most willingly helped in all my efforts, and every means of encouragement have been afforded me. Two facts seem constantly forgotten in the discussion of this subject. One is the limited powers possessed by the vestry, and the other the exceeding carefulness—even unto fear—exhibited by the magistrates in their decisions, and which almost invariably tend in favour of the defendants. Before concluding, I wish to draw your attention to what the Registrar-General says about the mortality in London during the two decenniads, 1841-1850 and 1850-1860. "The mortality increases," he writes, "in Islington from 19 to 21, where the population has nearly doubled its density; from 26 to 28 in St. Giles's, where the population is dense and stationary. In Stepney,

also, the mortality increased from 26 to about 27; in Poplar from 22 to 24; in St. James's Westminster, from about 22 to 23; in the majority of London districts the mortality decreased. The decrease was considerable in nearly all the districts on the south side of the Thames, except in Wandsworth and Lewisham, where the population became much more dense in the second than it was in the first decenniad." You will perceive, again, that where there is increase of population there is increase of mortality. This district is more densely populated than any other on the southern side. I must remind you also that the Registrar-General stated in the weekly Returns of Births, Deaths, and Causes of Death in London during the year 1862, "the south districts have achieved for themselves a marked improvement." Sanitary science does not come forth at once fully equipped and in perfection; it is a growth,—a growth like that of our political and other systems which maintained a permanency. The system under which we did live before the establishment of vestries had grown for centuries, and we are ripe unto rottenness. The cholera stayed the continuous culture of this harvest; and now we are engaged in another but as yet have barely begun to sow; our far off descendants will have to reap the harvest.

Mr. Elliott moved the adoption of the report. Under ordinary circumstances, he said, he should move that the report should be received and referred to the committee, as was usual with the Medical officer's report; but he should now propose to deal with it at once, for the vestry during some time past had been exposed to a stream of calumny in the press. The report of the Medical officer was the best answer to, what he maintained, had been a gross perversion of the truth in the reports and statements which had gone forth to the public, some of which had emanated from members of the vestry, who had designated those opposed to them as the "rest and be thankful class." The parish, he maintained, was very healthy, considering its dense population, and he added to his motion for the adoption and printing of the report for circulation a second clause, giving a vote of thanks to the Medical officer.

There was a warm discussion as to who should second the motion. At length,

Mr. Archer seconded the motion, and he declared that the press was hoaxed in giving currency to the reports which had lately appeared.

Mr. Bash, who spoke amid considerable interruption, said that there was no question as to the sanitary condition of the parish being most wretched, and he urged that the vestry should look the matter fairly in the face, so as to be prepared to remedy the defects which existed. There was no properly appointed sanitary inspector in this distressed parish, where there were so many ill-ventilated and ill-regulated houses; but the duty of inspecting those places was left to one or the other of officers who had distinct and separate duties to perform. There was no one to see that the scavengering and dusting contracts were properly carried out, and no one could stand up in the vestry and say that the poor districts were in any way properly supplied with water.

Mr. Beadle supported the resolution, and after addressing some warm observations of a personal nature to vestrymen who had described the sanitary condition of St. George's in print, he went on to ask how it was possible for the vestry to help the poor people in these ill-ventilated and overcrowded dwellings. He had made inquiries himself, and he found a widow with six children living in one of these wretched dwellings. The income of the family amounted to 12s. a week, out of which 1s. 9d. was paid for the room they lived in. The parish could do nothing, for the parish had not the power of pulling down these wretched houses, and the places, which were much improved of late, owed their bad state to the inhabitants themselves, and if the landlords were to be compelled to "beautify" these dwellings—he used the word for want of a better—and to follow up repairs, they might as well throw up their property. With respect to the naked child shown in the picture in the 'Builder' as running about Maypole-alley, he might mention that he had made inquiries, and he had found that one day a man with a moustache, and looking very much like a foreigner, came down the alley, and while he was there the child, who was undressed to be washed, ran out into the court for an airing (a laugh); and so it came to pass that it was shown in a paper that in the 19th century children ran about Southwark in a state of nudity.

Mr. Bransby, in illustration of the want of sanitary inspection, described a place to which he himself had called attention—a spot where there was a waggon-load of vegetable and stable refuse, and which remained for more than a fortnight after.

Mr. Rendle said the Medical officer's report was the answer of the majority of the vestry, and as such he was willing it should go forth. In the course of his speech, which was greatly interrupted by personal remarks, he went on to show that there had been, by the statistics of the physician to the Fever Hospital, 400 cases of fever in the parish, when, if there had been proper sanitary arrangements, there would not have been 100. He pointed out, amid a running commentary of jokes and laughter, that fever occurred over and over again in the same houses; that people were taken from a house to the Fever Hospital, and that uncontaminated persons were permitted to inhabit that house without any means having been taken to purify it; and this, he maintained, was little short of manslaughter on the part of those who should look after the sanitary condition of this crowded portion of a large city. The cholera, he warned them, was said to be coming—a disease for which there was no positive remedy except prevention, and he earnestly urged them to be warned in time. He was in favour of the report being printed, but he disagreed from the motion for giving a vote of thanks to the Medical officer.

After a very long discussion the motion was carried. It was understood that the question of the sanitary condition of the parish would come before the assembly on a future meeting in a report from a committee.

MEDICAL NEWS.

Medico-Psychological Association.—At the last meeting of this Association, Mr. John A. Blake, M.P. for Waterford, was by those present unanimously elected as an honorary member "in grateful acknowledgment of his efforts to improve the position of their branch of science." This distinction, rarely accorded to anyone outside the medical profession, could not have been more deservedly bestowed. On all questions affecting the medical and moral treatment of the insane, the regulations of asylums, and the care of a largely increasing class of sufferers, Mr. Blake has manifested an accurate acquaintance with the principles of psychological science, and enlarged views as to the obligations which insanity imposes on those entrusted with their care. In Parliament by his personal influence, out of Parliament by his able writings, he has awakened public attention to the condition of our asylums, with a view to their better, and more efficient regulation. Mr. Blake has for some months past been personally inspecting the Lunatic Settlement of Gheel, in Belgium, and has also visited the State asylum in Turin, and similar institutions at Genoa and other continental towns, with the view of contrasting their several systems of treatment and management, as preliminary to the introduction of legislative measures in the coming session of Parliament.—'Lancet.'

Medical Journalism in America.—It is a matter of notoriety to those who have ever had personal interest in this matter, how unsatisfactory and unremunerative is editorial and publishing labour expended on medical journals Why this should be so is difficult to explain; it is true that a very small proportion of the medical population of the country feel the necessity of a medical journal; that, too, seems strange to most of us who have access to journals. Before the outbreak of the rebellion there were a large number of medical journals in America—every considerable city had its medical organ—and many cities sustaining medi-

cal schools had several journals. We had more journals than were pecuniarily sustained by their subscribers, and we fear more than were worthy of support. The number rapidly declined with the war, so that from about fifty we only have about ten or twelve at the present time. This large suspension wrought its benefits as well as its evils. One of the benefits is that probably the surviving journals are on a firmer basis than ever was secured by medical journals in this country, and therefore in a condition to be more independent and useful. One of the evils is that important cities and sections for a time have been entirely unrepresented in medical journalism, but that will speedily correct itself with the return of peace and the reduction of the expenses of publishing; indeed, the probabilities are that we may soon have a revival of schools and journals, and especially that worst of professional evils, journals devoted to the *clique* interests of schools, as abundant as leaves in Vallambrosa.—'Cincinnati Lancet and Observer.'

BETHLEM HOSPITAL.—Among the charities of which the Charity Commissioners have recently obtained a special account is this great hospital, which stretches across so large a space in what were once St. George's-fields, but now a part of busy London. Bethlem comprises a foundation applicable to the general purposes of the hospital, and, in fact, devoted to the treatment of patients deemed curable, and a foundation for the maintenance of incurable lunatics. The department for criminal lunatics, maintained by the Government, is no longer required, a state asylum at Broadmoor having been provided. The estates and other endowments of Bethlem produce a gross income of 18,000*l.* or 20,000*l.* a year, a third of which comes from estates in Lincolnshire given in 1729 by E. Barkham for the maintenance of incurable lunatics. Mr. F. O. Martin, who has made the inquiry into the affairs of Bethlem, submits that as incurable lunatics are now provided for by county asylums, the Lincolnshire estates should be transferred to the general fund. He has to state that there have been times, and not very remote, when the management of Bethlem has not been altogether creditable to the aldermen, common councilmen, and nomination governors bearing rule over it. The tavern bills he pronounces "not justifiable." In the period from 1817 to 1836 the Lincolnshire rental yielded 105,673*l.*, and only 32,110*l.* found its way to the coffers of the hospital; but the expenses of the sea banks and of the estate in general have now very greatly diminished. The "arrangement" made on the discovery of the embezzlement practised by the former receiver, Mr. Hudson, has a very ugly look. Mr. Hudson was also prothonotary of the Court of Common Pleas, and when he absconded the Treasury seem to have made some demur to the payment of his pension under the Act of Parliament. But a receipt was produced, signed by the treasurer of the hospital, for 3,000*l.* agreed to be received in discharge of all demands, and the pension of 2,000*l.* a year was then ordered to be paid to Mr. Hudson. Mr. Martin is able, however, to report that no one can fail to be struck with the great improvements which have been made in the management of the hospital. It is now, he says, under the ordinary jurisdiction of the Commissioners in Lunacy, and regularly inspected by them. In 1841 only 23·60 per cent. of the patients attended chapel on Sunday, and there was a weekly average of 2·64 per cent. under restraint; in 1862, 55 per cent. attended chapel, and restraint had been for several years unknown. Of the 115 curable patients in the hospital in 1862 only eight were unemployed, and of the 61 incurables 24. The cost per head of the patients appears to have increased, but the increase may be well accounted for by the rise in the price of provisions and other articles, and the more liberal arrangements for the comfort of the patients. The cost of maintenance, furniture, and clothing was rather over 36*l.* per head in 1862. The propriety of the expenditure on buildings and repairs involves a question upon which there is difference of opinion; the Commissioners in Lunacy and some of the governors holding that it is expedient to dispose of the present building and to remove the hospital to the country, while others consider that it should be retained where it is. It is expressed in the instructions for admission to the hospital that preference will be given to patients of the educated classes, to secure accommodation for whom no patient will be received who is a proper object for admission into a county lunatic asylum.

THE WILL OF SIR WILLIAM HOOKER.—The will with a codicil of Sir W. Jackson Hooker, Knight of the Royal Hanoverian Guelphic Order, late director of Kew Gardens, was proved in the London Court on the 18th instant. The executors are his widow, Maria Hooker; his son, Joseph Dalton Hooker, M.D.; and Mr. Thos. Brightwen, of Great Yarmouth. The personal estate was sworn under 35,000*l.* The will is dated 17th December, 1859, and the codicil 12th of September, 1862. Sir William died at Kew Gardens on the 12th of August last. The bequests are entirely of a family nature. To his wife Sir William leaves his furniture, plate, wines, &c., a legacy of 300*l.*, and the interest of 5,000*l.*, which is to be set apart to meet the annuity. Sir William leaves to his son, Dr. Joseph Dalton Hooker, his books, prints, pictures, collection of plants, and botanical specimens. The residue of the estate is bequeathed in specified proportions between Sir William's son, his daughters (Mrs. Evans, the wife of Dr. Thomas Robert Evans; and Mrs. M'Gilvray, the wife of the Rev. Dr. M'Gilvray), with provision also for the children of his son and daughters. It appears by the codicil that Sir William has also made provision, by way of settlement, for his granddaughter, Mrs. Gardner, the daughter of his deceased son, William Dawson Hooker, subject, however, to a life provision made for the widow, Mrs. Isabella Whitehead Hooker.—'Pall Mall Gazette.'

THE CHOLERA IN THE MEDITERRANEAN.—A Correspondent of the 'Times,' writes as follows, from Valetta:—The cholera appears to be slowly wearing itself out. A decided improvement took place on the 1st of September, as shown in the bulletin made up on the morning of the following day, when the number of attacks fell from 45 to 18, and the deaths from 25 to 9. The great heat had very much abated on that day, when the island was refreshed by a strong and cooling breeze. On the two following days the number of cases rose again, but showed a falling off on the next day. Since then the epidemic has been on the whole decreasing. For the week ending the 10th inst. 129 attacks were reported, against 239 for the week preceeding. In the crowded city of Valetta there have been scarcely two cases a day on the average during the week, and none to-day. The weather is becoming cooler, although the thermometer is rarely below 80 deg. In consequence of cholera not having entirely left Cairo and other parts of Egypt foul bills of health continue to be issued at Alexandria. The sanitary state of Greece is good. The official journal of Sicily says that the sanitary state of that island is satisfactory. From Marseilles we learn that the spread of cholera in that city was causing much alarm, and many of the inhabitants had fled. There were several cases on board the last Peninsular and Oriental Company's steamer, and one of the firemen, an Englishman, died on the day before her arrival at Malta. Letters have been received to-day from Constantinople, *viâ* Alexandria, to the 24th and 31st ult. The first speak of a diminution of the cholera and the partial resumption of business at Galata. The letters of a later date mention, however, that a fresh outbreak of the disease had occurred, and that every day the returns reported a larger number of victims, so that fears are entertained that the epidemic had not yet done its worst.

THE CATTLE DISEASE IN DERBYSHIRE.—It seems to be doubted by many practical as well as eminent scientific men whether the alleged "Russian plague" has really reached the shores of England. An opinion is gaining ground that the cattle disease, which undoubtedly exists in some localities, is attributable to atmospheric or local causes. However this may be, and though doctors differ on the subject as wide as the poles are asunder, it is always wise—whether the disease be of the typhoid type or some mysterious visitation—to take all rational precaution to prevent its extension. With this view we are glad to see that Derbyshire and other counties are up and doing. Mere talk will not

accomplish anything. A vigilant inspection, and other precautionary measures are required, and every man, whether buyer or seller, should act as a sanitary inspector. Every man should consider himself bound to act as if he had a presentiment that the disease was floating in the direction of his own herd. The disposer of a diseased cow, or the purchaser of it, if they are conscious of the fact, ought to be punished with the utmost rigour of the law. At a meeting of the "Cattle Plague Insurance Committee," held at the County Hall a few days ago, Mr. Evans, M.P., and Mr. F. Wright subscribed 500*l.* each.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, OCT. 4.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Obstetrical Society of London, 7 p.m.—Council.—8 p.m.—Dr. Marion Sims, "On Inversion of the Uterus;" Exhibition of Bandeloque's Original Cephalo-Tube; Mr. Lowton, "Vascular Growth of Funis," and other papers.

THURSDAY, OCT. 5.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, OCT. 6.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, OCT. 7.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

MONDAY, OCT. 9.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metropolitan Free Hospital, 2 p.m.

TUESDAY, OCT. 10.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Observations in Medicine in the Art of Case-Taking. By J. S. Warter, M.D. London: Longman and Co., Paternoster row.

Clinical Memoranda. By W. Hinds, M.D., No. 1: On Pericarditis and Pericardial Murmurs. Birmingham: A. B. Matthews, 71 New street.

On the Speedy Relief of Pain and other Nervous Affections by means of the Hypodermic Method. By C. Hunter. London: John Churchill and Sons.

History of an Unsuccessful Case of Amputation at the Hip-Joint. By J. S. Gamgee. London: John Churchill and Sons.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the office of the Journal, No. 27 King William street, Strand,

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office

THE OBSTETRICAL SOCIETY OF LONDON.—The notice and report have been received.

H. W.—If Mr. Clapp signed the certificate without seeing the patient, he was no doubt amenable to the observations referred to, but is it the fact that he never saw him, and signed the document only on the representation of a third party?

DR. T. R. TORBOCK.—The letter is inserted.

A VOICE FROM LIVERPOOL.—We have referred to this subject in another part of the Journal, and it will be perceived that we lean to the opinion expressed by our correspondent.

A STUDENT.—We have already stated that the registration at the Branch Registrar's does not supersede the necessity of registering at the different licensing bodies, at which the registration is carried on as heretofore.

GRIFFIN TESTIMONIAL FUND.

To the Editor of the Medical Circular.

SIR,—The following subscriptions have been further received on behalf of the above fund, which will be closed on Oct. 31st proximo:—

	£	s.	d.
Dr. Cuolahan, Bermondsey . . .	0	10	6
Dr. W. Sanders, Gravesend . . .	1	1	0
Amount previously announced . .	127	11	9
Received at 'Lancet' Office . . .	9	9	0

Yours obediently,
ROBERT FOWLER, M.D.,
Treasurer and Hon. Sec.

145 Bishopsgate st., Without,
Sept. 28, 1865.

MR. J. N. RADCLIFFE.—The memorial is inserted.

GENERAL MEDICAL COUNCIL.
32 SOHO SQUARE, LONDON, W.
September, 1865.

Registration at the Commencement
OF PROFESSIONAL STUDY.

NOTICE is hereby given, that Regulations for the Registration of Medical Students have been sent to all the recognised Schools of Medicine in England. Students commencing their studies are directed to apply to the Registrar for England, according to the Form with which they will be supplied on application to the several Qualifying Bodies, or at the Schools of Medicine and Hospitals.

General Council of Medical Edu-
CATION and REGISTRATION of the UNITED KINGDOM,
32 Soho square, London, W.

NOTICE.—The copy of the MEDICAL REGISTER to be printed and published in 1866 as directed by the 27th Section of the Act, will contain those names only which appear in the General Register as existing on the 1st day of January, 1866.

It is particularly requested that claims for the registration of first or additional Qualifications, and notices of alteration of Residence, may be sent to this office as soon as possible.

October, 1865.

Royal Orthopædic Hospital for
CLUB FEET, SPINAL AND OTHER DEFORMITIES, 315 Oxford street, W.

Mr. Tamplin will deliver a course of lectures on the Nature and Treatment of DEFORMITIES, at this hospital, commencing Monday, Oct. 23, at half past two o'clock until completed, legally qualified practitioners are invited to attend. Tickets may be obtained from the Secretary at the hospital.

Pupils are admitted to witness the practice of the hospital on the following terms, for six months 3*l.* 3*s.*; 12 months 5*l.* 5*s.*; perpetual 10*l.* 10*s.*

"A third Year's Student of a London Hospital thoroughly accustomed to Dispensing, wishes to give his services as a Dispenser &c., in exchange for board and lodging, with liberty to attend lectures."

Address, G. A. care of Mr. Wm. Howell, 10, Broad Mead, Bristol.

The Dairy Company (Limited).
Capital, 100,000*l.*; in 10,000 Shares of 10*l.* each. Deposit, 1*l.* per Share.

DR. LANKESTER, F.R.S., Chairman.
Professor Gamgee, Superintendent.
Mr. S. S. Dancocks, Manager.
BANKERS—London and County Bank, and Branches.

This Company is formed at the present juncture to supply the public with guaranteed new milk.

The Directors desire to draw attention not only to the sanatory results that a pure supply of milk must produce, but, that The Dairy Company, considered simply as a Joint Stock enterprise, affords a profitable and secure investment to its Members.

From calculations based upon well considered data, the Directors can confidently assert that the operations of this Company will yield highly remunerative returns.

Detailed Prospectuses, with Forms of Application for Shares, may be obtained at the Temporary Offices of the Company, Moorgate street Chambers, E.C.

Should no Allotment be made, the Deposits will be returned in full.

The Dairy Company (Limited).
NOTICE IS HEREBY GIVEN, that the Share List of this Company will close on Saturday, October 7th.

By Order.
H. S. HIRD,
Sec. pro tem.

Moorgate street Chambers,
30th Sept., 1865.

THE JOURNAL OF PRACTICAL MEDICINE & SURGERY

FOR SEPTEMBER IS NOW READY,

AND CONTAINS—

Refrigeration of the Air in Dwelling-Houses and Public Edifices; Thoracentesis; Preservation of Life in New-Born Infants before the Establishment of Respiration; Dangers of the Present System of Registration of Births in France; Death and Obsequies of M. Beau; Thoracentesis; A Synopsis of the Cases observed during the Year 1864-65; Remarks on Fibro-Plastic Tissue; Treatment of Rheumatic Fever; Treatment of Infantile Strophulus; Thoracentesis; Application of Caustics in Phlegmon; Pathology of Sympathetic Ophthalmia; Arterial Hæmorrhage arrested with Ergotine; Treatment of Cholera; Sedative Lotions in Cancer; Ovariotomy; Thoracentesis; The Wild Man of the Var; Pathology and Treatment of Stricture; 'The Grape-Cure,' by J. Ch. Herpin, M.D.; 'Improvement of the Human Form,' by —Dancel, M.D.; Promotions in the Legion of Honour; Cholera; Preservation of Ice; New Edition of the French Pharmacopœia; Effects of Cast-Iron Stoves.—Obituary; MM. Beau, Bouchez, Dieudonné, Karl Pagenstecher, &c.

This Journal, published at the end of every month, in the French and English languages, has the largest circulation of any Medical periodical in the world.—Sent on receipt of 13 stamps. Annual Subscription, 13s. post-free.

OFFICE—20 KING WILLIAM STREET, STRAND, W.C.

BLOCKEY'S LONDON STOUT

NOURISHING LONDON STOUT

DR. HASSALL'S REPORT:—"I have carefully analyzed Blockey's well-known Stout, as obtained from 21 Duke street, St. James's, and find it to be a genuine, most wholesome, and highly nourishing beverage, less heavy, and consequently more digestible than London Stout in general.—Signed, ARTHUR HILL HASSALL, M.D London, Analyst of 'The Lancet' Sanitary Commission." Casks of 4½, 6, 9, and 18 gallons, at 1s. 8d. per gallon; 3s. per dozen pints; 5s. quarts.

RAGGETT, late Blockey, 21 Duke st., St. James's. Established 100 years.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 78 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments forwarded for 6 stamps.

Photography.—Mr. G. R. Fitt, 100 Quadrant, Regent street, W., offers advantageous terms to Members and Students of the Medical Profession who may favour him with sittings.

All Sizes of Portraits taken daily.

Mr. Fitt, who was for some years a student of the Profession, devotes personal attention to Photographing Morbid Specimens and other subjects for illustration.——The attention of Students and others is invited to Mr. Fitt's Series of Portraits of Eminent Lecturers and Teachers at the Metropolitan Medical Schools. See notice in THE LANCET of Nov. 26th.

G. R. FITT, 100 Quadrant, Regent street, W.

The Portraits may also be had of ROBERT HARDWICKE, 192 Piccadilly.

William Hawke, Wild Court, Great WILD ST., DRURY LANE, LONDON W.C., (late Ansell and Hawke), Manufacturer of every description of Shop Fittings, Dealer in Medical Glass, Earthenware, and all kinds of Shop Utensils, Medical Labelling, Writing, and Embossing on Glass.

Drawings, Specifications, and Estimates furnished for Fitting-up Druggists' Shops and Surgeries with every requisite, and for erecting Shop-Fronts. Druggists' Stocks and Fixtures valued.

Medical Fixtures and Glass Manufactory, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Altering in the above Profession, that he has an extensive assortment of SHOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc

---

Treloar's Kamptulicon, COCOA-NUT MATTING, AND OTHER DURABLE FLOOR COVERINGS, 67 LUDGATE HILL, LONDON, Three doors from the Railway Bridge.

Brass and Zinc Door-Plates.—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charge. Chemists' Shops fitted up with Window-sill Plates in the plain or Gothic Patterns. Lists of Prices post free.

Plates altered and repaired.—Country orders punctually attended to.

36 CHANDOS STREET, CHARING CROSS, W.C.

Geo. Smith and Co.'s Pure Extract of CALVES' FEET for INVALIDS and CULINARY USE. Sold in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Druggists, Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland street, Regent street Office: 94 Upper Thames street, E.C.

Pepsine and Pepsine Wine.—Boudault begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from is sole Agent, Mr. PETER SQUIRE, Chemist in Ordinary to the Queen and H.R.H. the Prince of Wales, 227 Oxford street, London, to whom all applications respecting it must be addressed.

Third Edition, with Further Remarks by Dr. CONVISART, Physician to the Emperor of the French, edited by W. S. SQUIRE, Ph. D.; published by J. Churchill, London; may be also had of the Author, 277 Oxford street, price Sixpence.

The Medical Circular.

INTRODUCTORY ADDRESS

DELIVERED BY

PROFESSOR PRIESTLEY, M.D.

AT

KING'S COLLEGE.

the Opening of the Medical Session, October 2nd, 1865.

Professor PRIESTLEY commenced his discourse with a eral history of medicine from the earliest period, and n proceeded to say: I have taken this cursory glimpse the history of Medicine mainly to point out that the nce of Medicine has been of slow and difficult develop- nt. Science comes not by intuition, it is the accumu- d experience, generalised into law, of whole generations thinking men who have devoted themselves to its study, an intimate acquaintance with it is absolutely indis- sable to him who would be a sound practitioner. One the most important Medical truths which has been ked from all the confusion of clashing hypotheses and less variety of opinion is, that in the human body resides wer which not only sustains and preserves it in health, enables it to oppose resistance to adverse influences, more than this, recovers it, if suitable conditions can procured, when stricken with injury or disease. This t truth was long ago pointed out by Hippocrates, and, gh often lost sight of for a time, now stands out as a ling star, clear and bright, to influence every proceed- of the scientific physician and surgeon. What the of attraction are to astronomy and those of affinity to nistry, such are those of what are termed vital force to icine. Without a due recognition and appreciation of e, the Medical practitioner would be constantly at fault, he one hand, over-estimating the power he possesses ontrol diseased action, or on the other going hopelessly ng in his efforts at cure. All the attempts at healing on part of the philosophical physician are based on an ac- ntance with that *vis vitæ*, that *vis medicatrix naturæ*, h pervades the living organism and preserves it in its rity. As he knows that Nature has ways and means liar to herself of throwing off the burdens imposed her by disease, that she is prepared for the storms as as for the calms of life, instead of prescribing remedies h may in theory be supposed to act specifically, homœpa- lly, or even allopathically, in uprooting illnesses, he en- ours to trace the source of the mischief, watches the indica- which points towards restoration and cure, and by all s at his disposal assists Nature to adjust the balance of h. Now mark how different this method of healing is from enerally supposed way to which diseases are combated ured. True, it may be said of the intelligent classes in ay that they are no longer deluded by the expectation iraculous interpositions for the cure of disease. ier do they rely on charms or amulets or astrological ols; but educated and ignorant people, in common, tain ideas of the art of healing which are entirely at ace with its actual state and progress, and which are o mechanical in their tendencies. The common im- on seems to be that all diseases are entities, which parasites attack the human body, or like poisons ot the fountains of life; and that the physician has, ght to have, or will have when the science is more ted, a specific remedy for each—a panacea for every al ill. We see indications of this bias at every turn, mon conversation, in our intercourse with patients; he press, so powerful for good or for evil, represents me idea, and in our daily and weekly newspapers we opied and re-copied details of cures by newly-dis- d specific remedies. Nay, further, certain heretical Medical writers, possessed by the same notion, while asserting that rational practitioners, whom they nickname "Allopaths," cannot cure diseases by antagonistic medicines, propose another method even more unsound—viz., to cure diseases specifically by medicines selected on the principle of "similia similibus curantur." Nothing can be more erroneous or more fallacious than this. The number of diseases traceable to morbid poisons is comparatively small, and the number of specifics we possess, or are likely to possess, is still smaller. And if we look closely into the *modus operandi* of a so-called specific—take quinine, for example, as a remedy for ague—it is very doubtful if it acts in any other way than as a poweful tonic, strengthening the vital force, and enabling it to oppose greater resistance to the invasion of disease. Indeed, in the large proportion of ailments which affect the human frame, there is no engrafting of a *materies morbi*, which can be attacked and destroyed like a parasite, or neutralised as we neutralise an acid by an alkali. The disease is rather the result of unnatural conditions of life, which have altered or impaired nutrition, and have ended in degeneration or destruction of the part affected. Thus the healthy performance of function is prevented, and inconvenience, pain, and death are the consequences. From this point of view the practice of Medicine becomes a much more difficult and complicated process than it is ordinarily supposed to be; for instead of being comprised in a number of recipes, or learning empirically what drug is best in this complaint or for that symptom, normal anatomy and physiology must be studied, the natural history of morbid changes must be mastered, the causes of disease understood, and the treatment in most cases must consist not so much in prescribing medicines as in ensuring those healthy conditions which will give Nature a chance of resuming her sway, and performing her own method of cure. I trust I may not be misunderstood. I would not lead the Medical student to trust so implicitly to the restorative powers of Nature that he despises the resources of art, or undervalues the services that medicines judiciouly administered may render in the treatment of disease. A wise physician has truly said: "There is no curing disease by art without first knowing how they are cured by Nature, but the parody is not true that the art of Medicine consists in amusing the patient while Nature cures the disease." Unfortunately, we have only to make acquaintance with this vital force, which possesses such wonderful attributes, speedily to learn that, unaided, it is many cases unable to oppose sufficient resistance to adverse influences, and is borne down and extinguished whenever the intensity of diseased action predominates, Nay, further, it is well established that this force, however salutary in its general operations, may, as the force which drives a locomotive headlong to destruction, when once it leaves its usual track, be so perverted as to lead to infinite mischief. On this point an eloquent friend has written: "Though Nature nits up wounds with her adhesive inflammation, by the very same method she glues the intestines into fatal entanglements, shackles the heart, and chokes up the windpipe. In this man she soothes the grief of a wound by pouring out serum; in that, she makes the same effusion effectually close the *rima glottidis*. She spirts blood from the hæmorrhoidal vessels of Paul, who blesses her for saving him from apoplexy; of which very disease poor Peter dies, because she pours the very same fluid into his lateral ventricles. And so on; for man's body is a microcosm, in which one sees the play of Zoroaster's antagonist principles. Nature is ever the same—blessings are mixed with curses; the poisonous berry and the nutritious root are found on the same plant; there are balmy dews and pestilent fogs, fertilising streams and destroying deluges, and the lair of the murderous lightning is in the cloud that floats across the blessed sunshine." Such, gentlemen, are the incongruities you have to understand and contend with. And in reference to the administration of medicines, and the other resources of art, be not led to discard them or disbelieve in their efficiency, when you learn that they cannot act specifically as you previously believed, or know that in numberless cases Nature will work her own cure unaided. In the operations of the surgeon and obstetrician, the bene-

fits are at once apparent in the removal of some cause of suffering, or in the deliverance from some imminent peril; and in the management of Medical cases by the physician, although the relation between cause and effect may not be so readily observable, yet the advantage is not the less real. Although he may have no specific for the poison of fever, he can assist its elimination by medicines which act on the excretory organs, he can palliate the distressing symptoms, and support the strength until the crisis is past; and in a case of pulmonary consumption, where no medicine can be expected to have the power of replacing the injured and lost lung tissue, he may yet hope to sustain the vital power, temper the amount of morbid action, and give Fature time to cicatrise and heal those yawning caverns he detects with such sad forebodings by the aid of his stethoscope. In treating diseases the physician is as a rule, if I may so speak, in the position of a constitutional Minister, only in exceptional cases in that of a master. He interprets Nature's wants; removes hindrances out of her way; sometimes, it may be, restrains and controls her. A sLord Bacon expresses it, "he is the servant and interpreter of Nature, and feels that he can only understand and act in proportion as he observes and contemplates the order of Nature. More he can neither know nor do." The function of the Medical practitioner is not, however, confined to the treatment of diseases and injuries *in præsentia*. A new department of science has sprung up, little known to the ancients, and which has been almost created in our times, called "preventive medicine." In this the Medical practitioner has an almost illimitable field for the use of his talents—unbounded scope for the exercise of benevolence and philanthrophy. On him now devolves the duty of tracing upwards to their very well-springs those death streams which, small and imperceptible at first, converge to swell the flood of preventible mortality, and to stem them it may be, before, by widening, deepening, and strengthening, they overwhelm whole communities of our fellow men. And it is not alone the Medical officer of Health who is privileged to ward off dangers which everywhere beset individuals and families. The physician, surgeon, the general practitioner however humble their sphere, have, as they move about among their patients. incessant opportunities of diffusing a better knowledge of the laws of health, and inculcating more intelligent views as to the way in which derangements in the animal economy are properly adjusted. In these boasted days of intelligence it is marvellous to contemplate the dearth and destitution of sanitary knowledge which prevails among rich and poor, and the carelessness or wilfulness which is evinced in matters of vital importance to health. It has always seemed to me that there is much in common between the duties of the clergyman and Medical man. They divide together obedience to the Divine command, "Preach the Gospel and heal the sick." One-half the duty of the Medical man consists in teaching and preaching how people may, in a physical sense, lead better lives; and if his heart be in his work, as he sees young and old stricken down by diseases which might have been prevented, "he burns with a passionate earnestness to bring back the bodily economy to its allegiance to the Supreme Guide," just as the conscientious clergyman of the Gospel yearns to bring back the erring soul to its Maker. And, rely upon it, the healing art is in more than one sense, as it has been designated, "the right arm of the Church;" for if it makes men stronger, long-lived, and healthier, it will make them also wiser and happier and better Christians. It will be within your province, putting aside your own selfish interests, to instruct the mother how she should feed and clothe and nurse her tender infant, so that that terrible mortality bill may be lessened which tells us that one child in every three dies before the completion of its fifth year; to counsel the young how they may best attain a vigorous and healthy adult life; to persuade the wealthy to enjoy their riches moderately, and thus avoid the ailments incidental to a too luxurious living; to teach the poor how with scanty means good ventilation and cleanliness, with sobriety, are the more necessary, and that the open sewers and dust heaps at his very door are hotbeds for pests and fevers; to shame the landlord who, for greed of gain, lets tenements to the ignorant poor so unwholesome that he would scarcely keep his own dogs in them; to stand between the utterly destitute, who have sickness added to poverty, and the overseers or guardians, who, it may be, are more careful about the increase of rates than the relief of distress; to warn employers who crowd their workmen and women in close rooms that they are wholesale demoralisers of their species, and that the employed, under such circumstances must break down in health, or go to the gin-shop to palliate the effects of foul air; to intercede with an over-parsimonious Government for an improvement in the diet and lodging of soldiers and sailors; in a word, to "carry hygiene into the army, the factory, and the nursery, down rivers, and across fields." And how, gentlemen, are you to qualify yourselves for these great duties, for these great responsibilities? Long ago Hippocrates wrote that there were four qualities indispensable to every good physician; and in using the appellation physician he used it very generically, as I do to-day, and included all Medical men. These qualities were Learning, Sagacity, Humanity, and Probity; and although this aphorism was put on record before the commencement of the Christian Era, it is just as true now in the middle of the 19th century. Professor Priestley then dwelt at some length upon these necessary points, and notably upon the great advantage which a Medical man derives from education. He then observed: The Medical man must ever be acting on probabilities, often seeing "as through a glass darkly;" and yet he must act promptly and decisively, as though dealing with certainties. Can it be wondered at that Medical opinions should sometimes be erroneous—that mistakes should ever and anon be committed even by the most skilful? It is, I suspect, only those physicians and surgeons who have no practice who never make mistakes; those of large experience often find themselves at fault. Medicine shares uncertainties with many other professions, however with politics, with ethics, with law, and navigation; and although our brethren of the bar may not because doctors differ, we may instance with equal force the glorious uncertainties of the law. "Medicine," as Dr John Brown says, "is a tentative art, to succeed in which demands a quickness of eye, thought, tact, and invention exercised by patient observation;" and the Medical man must have that fertility of resource which is not baffled whenever a case arises which seems not defined by the rules of art. There is no better training for the emergencies of future practice than that afforded by the out-and in-door departments of a general hospital, and the student, however industrious, who does not constantly test his Medical knowledge at the hospital, and, as gold in the refiner's fire try it at the bedside of the patient, is very apt, in after years of practice on his own responsibility, to find every case an exception to the ordinary definition of disease laid down in the class-room or in class-books, and to be constantly at a loss how to proceed. He is, as Montaigne says, "like him who paints the sea, rocks and heavens, who draws the model of a ship as he sits safe at his table; send him to sea, and he knows not how or where to steer." Some short time ago I heard of a physician, of well-deserved reputation, who was summoned to the bedside of a little child, evidently acutely suffering. He was well versed in that language of signs by which alone we can gain information for guidance in the ailment of infants; but after careful examination *secundum artem* he failed to discover what ailed the child, and had the rare courage to say so. He expressed his interest and perplexity, and promised a return. The loss of a train or some other accident brought him back more speedily than was expected, and he carefully sat watching the writhing of his little patient. In some time, he began carefully to feel inch by inch the whole surface of the child's body. The friends thought him mad, but watched with redoubled anxiety. Suddenly he exclaimed, "Here it is!" His fingers had encountered something, and the child evinced still greater anguish. The enemy was a broken pin, deeply imbedded near the spine, which was speedily extracted, and the mystery solved. The practice of medicine, both in reference to the prevention and cure of disease, consists much more in

exercise of common sense than is usually supposed ; and sagacity in medicine often becomes more conspicuous in the exercise of common sense, than any of the so-called special senses. Again, the Medical man must have humanity —a genuine sympathy for those who are sick and suffering. The exercise of pure science and art will often have but a very partial influence for good, unless you can pour balm upon the wounded spirit, and give that hope and encouragement which is so important a help to cure ; and if it be true, as I believe it is, that a remedy may be useful when prescribed by one physician and inert or powerless when prescribed by another, simply because the one exerts a more powerful moral influence over the mind of his patient, it is one of the greatest importance to study carefully the minds of men, to dip down into the depths of our common nature, and thus be able to strike with strong and yet gentle touch the cords of sympathy which make us all akin, and in our conversation with patients thoughtfully to consider before speaking, lest perchance our way of saying a thing may do more harm than our prescription can do good. True it is that, in deciding what is best for a patient, we must allow our judgment to be biassed by nothing which would militate against his chief good,; the pure white light of science must be tinctured by no coloured rays which may disturb mental vision ; but the physician may permit the admission of those warming rays of sympathy and kindliness which so often gladden the hearts of patients, and may cheer and console even those he cannot cure. The sick bed levels all distinctions, and you may evince as much chivalry, and reap as large a reward of satisfaction, in easing the pain and soothing the pillow of the poor, in conscientiously taking charge of the destitute, as in attending a richer patient, who thinks he has discharged all his obligation to you when he has paid his fee. I would fain impress on all hospital pupils how great is their responsibility, and at the same time their privilege, when they are entrusted with the care of the sick poor. Their steady and punctual work, their cheerful readiness to act in emergencies, are almost as essential to the well working of a hospital as efficient services from the Medical officers. And in justice to Medical students, I can testify that they are seldom found wanting. And what can I say of probity that you do not all know? Is not truthfulness always desirable? Is not honesty the best policy in all professions and occupations? I may be excused for dwelling a moment on this quality, because the Medical man is exposed to unusual temptations, and the very nature of his pursuits makes even self-deception easy. The defective knowledge of physiology, and of the scope and power of the Medical art, which prevails in the community—the whims and caprices of patients—the demand for specific methods of cure—render it extremely difficult for the Medical man, conscientious though he be, to steer a straightforward course. He perhaps very soon discovers that it is far simpler, less laborious, and more remunerative to pander to popular prejudices, and that in the end he gets little credit for the various attempts he makes to treat patients on rational principles. Most likely he is charged with being of the old school, and behind the advance of science. Under another form, the spirit of Naaman the Syrian most extensively prevails, "Did not I think he would give me some specific remedy for my ailment, instead of indicating so timely a way of cure?" It is but too true that any designing charlatan who will proclaim an infallible and newly-discovered cure finds numberless votaries ; and if he be shrewd enough to make no gross mistakes; Nature will help him to a certain number of recoveries, notwithstanding the worthlessness of his method. "The spontaneous curability of most diseases is to the Medical charlatan what the regular and calculable, but generally unlooked-for, recurrence of certain natural phenomena is to the juggler and mountebank." It is as though a civilised traveller thrown among savages, predicted a solar eclipse, and claimed the fulfilment of his prediction as testimony of his power over nature. And it is not alone the uneducated who are led astray by the pretensions of quacks It is not long ago that the British Parliament gave a subsidy of 5,000*l.* for a specific for stone, the main ingredients of which, as it turned out, consisted of eggshells and snails. It is not forty years ago since an ignorant and notorious quack, called St. John Long, who was twice tried for manslaughter, made an income of at least 13,000*l.* a year out of the credulity of dupes in this metropolis. One noblemen was so deluded by this charlatan, that he swore at one of his trials he had seen him draw several pounds of a liquid like mercury from a patient's brains ! But now, at our very doors, we have had a pest of quackery polluting the moral atmosphere with its presence, which all our appeals to magistrates and vestries could not remove, and which was at least extinguished, not because there was a scarcity of dupes, but because the promoter was fool as well as rogue, and laid himself open to an action for mal-practice. It has been well said, "if physic be a trade, it is a trade of all others the most cut out for a rogue." To some people, a new sensation in medicine is as necessary as a new hat or a new bonnet, and sooner than not be gratified in their desires, they will accept the most exaggerated theory as eagerly as they will don the most extravagant costume. We have had "brandy and salt" cures, "movement cures," "mesmeric cures," homœopathic and allopathic cures, cancer cures without number We know not what may come next. Truly, exclaims a Transatlantic *confrère*, the Medical man and particularly the struggling one, has need to pray that he may not be led into temptation ; but if he has none other than sordid motives, his prayer is an useless mockery. It is as though he should beseech to be saved from poison, which he is swallowing voluntarily and of his own accord. Better the little produced by honest and unpretending industry, with conscience preserved bright as a polished shield, than to rise out of a slough dishonoured, clutching it may be the coveted prize, but covered with the filth and degradation of its surroundings. Then, besides the acts of open dishonesty, there are so many covert ways which may be practised by him whose conscience is not over sensitive He may exaggerate a patient's condition either to magnify his own skill, or as a worldly wise man once said "to make the most of him." If not scrupulous, he may employ a diversity of means to undermine the skill of a brother practitioner, and then dispossess him of his charge. The Medical man has no right to sacrifice the patient's true interest to trifling punctilios, but he has equally no right to deprive another practitioner of his patient by wily arts and mean insinuations. The relation of doctors to their patients, and of doctors to each other, cannot but be complicated, seeing that there are often many contending interests, and whole volumes have been written on what are called Medical ethics. All the rules of Medical etiquette are, however, intended merely to be the application to particular circumstances of that great precept, "Do unto others as you would that they should do unto you." In conclusion, the lecturer dwelt upon the necessity for the students to pursue study diligently, and with a just estimate of its importance. He assured them that if they persevered in well-doing they would ultimately reap their reward.

UNIVERSITY COLLEGE.

Introductory Address by Mr. Marshall, F.R.S.

The lecturer commenced his address by explaining to the student the importance of being able to distinguish between what constitutes science and what art in the exercise of his profession. He would meet with a series of individual problems, or cases, each suggesting two primary questions —viz., what is the matter? and what is to be done? Other questions would arise, as to the result of an individual case, its duration, its causes, and the mode of preventing its recurrence. Two of these questions only can be solved by art, and the remainder by science. The causes, the nature, the progress, and the result of a disease belong to the science of pathology, whilst questions of treatment and prevention appertain to the province of art. It is true that the terms Medicine and Surgery as they are commonly used, imply a combination of science and art, which here mutually aid each other ; but it is important to discriminate between what is science and what constitutes art. Science observes facts, and induces from them principles

and laws, whilst art is engaged in forming and treasuring up precepts, and rules of conduct or action. Hence Medicine and Surgery consist really of the science of pathology, and of the arts of therapeutics and hygiene. Besides this, the physician and surgeon are called upon to exercise other functions—namely, that of scientific expositors on questions of public interest, such as those relating to legal Medicine and legislative Medicine ; that is to say, in the administration of justice and in the art of government. But the immediate purpose of the present lecture was to illustrate the special aspect of Medicine and Surgery considered as arts, and to treat science only as having relations to those arts. By some it may be considered that this view of Medicine and Surgery derogates from their high positions ; but, from a certain point of view, an art may be regarded as being higher than a science. Science initiates, but art fulfils ; science is knowledge, but art is work ; science teaches or unfolds the laws of nature to the mind of man, who is merely recipient and reflective in the process : but in the exercise of an art man becomes a centre of operation himself, according to that amount of free will or independent agency with which he is endowed by Providence. The student of science may gain esteem as the possessor of learning, but the practitioner of an art attains a higher dignity in the exercise of his direct functions upon the world without. The place of the Medical and Surgical art is quite peculiar : it is not constructive, like the acts of architecture or ship-building ; it is neither a fine art, like music or painting or sculpture, nor is it merely one of the useful arts ; neither is it a destructive art like that of war. It is preservative, and approximates at one point—viz., in its department of hygiene, to the arts of floriculture and agriculture, which take care of vegetable organisms ; but, as a direct curative art, exercised upon living beings, and especially upon man, it holds a peculiar and noble position amongst the arts.

In the second place, the lecturer alluded to the limitations of this art, pointing out especially that, being exercised on individual living units, its limit of action coincided with the life of those units. He also indicated forcibly that in each living creature there resided a germ force, a metamorphic force, or formative force, which is in reality the only conservative and preservative force known in the body. With this, and this alone, the Medical art can act. Its efforts cease with the extinction or disappearance of this force. It is, indeed, the only limitation in this direction of the curative art. Another, but less important, element is the selection of the means and appliances of the art, which must be truly limited, though, to the human mind, they are practically incalculable. It is easy to perceive that the conservative power, or the so-called *vis medicatrix naturæ*, is the agent at work in the healing of an ulcer, or the union of a broken bone, but it is equally true in regard to every possible kind of disease or injury, external or internal. The physician or surgeon never cures a disease—he only assists the natural processes of cure performed by the intrinsic conservative energy of the frame, and this is but the extension of the force imparted at the origination of the individual being.

In the third place, the lecturer dwelt upon the relations of science to the curative arts, pointing out the necessity for an intimate knowledge of the living organism on the one hand, and the external agents incessantly acting upon it on the other. In this section of his address he insisted on the fact that man was, corporeally speaking, not merely in the world, but of the world—that if the world belonged to him, he also belonged to the world—that his body was subject to the physical laws of gravitation and cohesion, like other masses—that the elements entering into the composition of his body were in no way different from those that surrounded him, and that heat, electricity, magnetism, and light, permeated and operated within his frame —that the old idea expressed by the phrase of "ashes and dust" was abundantly illustrated at every step in advance of physical knowledge—that if we accept the doctrine of correlation of forces, according to which all the dynamical phenomena of nature are but manifestations of one eternal force, ever varying, ever transforming itself, but never suffering loss, or receiving gain, then, in the microcosm of the human body, the correlation of forces was manifested in even a more marked degree—and that if we regard the external world as composed of molecules or atoms acted upon by force, vibrating, rotating, or undulating for certain ends or purposes, so in the human frame there must be responsive movements equally intricate, or otherwise we should fail to perceive the external phenomena.

Lastly, science must be relied upon for the introduction of new remedies. By this line of argument the lecturer sought to show that though the student of Medicine need not possess an exhaustive knowledge of the sciences, still he must understand the general principles and more important facts of all the sciences, physical and vital.

In the second part of his address he drew certain practical conclusions from the views already adduced. He pointed out that it was the exercise of the *arts* of Medicine and surgery that was required by the public, and alone would be rewarded by them ; that these arts were confessedly imperfect—for all arts must be progressive, and their condition at any time must also be dependent on the state of science ; that, as arts, they give room for the exercise of individual aptitudes or qualities, and hence some attain the rank of masters in such arts, and to them, as in all arts—music, sculpture, painting,—pupils must have recourse to learn the rules and precepts the result of experience and tradition ; and lastly, that, as arts, they must be learned practically and by personal application. Books were useful as guides, and as stores of previous learning and experience, but they could never teach an art like that of Medicine or Surgery, which must be studied in the wards of an hospital.

With reference to the limitation of the curative art, the preservative force of the body, he adverted to the sacredness of life ; to the responsibility involved in the trust of health and life to the Profession ; and to the duty of preserving life by every available means. Furthermore he indicated the paramount importance of relying on natural curative processes, upon the preservative powers of the body, rather than upon too great medication, remarking that the multiplication of remedies had been held to be an infallible proof of the decadence of the Medical art. He urged, likewise, the careful exercise of a more natural treatment and avoidance of some remedies which might be acting injuriously in unforeseen ways, observing at the same time that as the whole frame sympathised with a local injury, so the entire organism must be co-operative in the cure of that injury.

Mr. Marshall then pointed out that the Pharmacopœia must be regarded as an inheritance from older generations by whom greater reliance was placed upon compound drugs, and stated that he believed the future tendency would be, whilst adding to the simpler substances of the Pharmacopœia, to diminish the number of compound formulæ.

Lastly, it was suggested that the complex relations between the outer world and the living man, with all the varied manifestations of force, acting and reacting on one another, should tend to teach us to beware of too strong adhesion to particular systems of Medical treatment. He further showed that those dogmatic methods seemed to the philosophic mind to be restrictions upon external nature, and that, in fact, they were restrictions placed upon the dogmatist's own mind. To those who abused the existing systems of Medicine, as worshipping the "idols of the schools," this would suggest a caution—viz., to beware, on the other hand, as Bacon also phrases it, of the "intemperance of systems." He then predicted that the future of physical science would afford a wide field for the discovery of new remedies, illustrating his position by reference to the singular slowness with which important remedies have been added to the therapeutical list, and the present addition of so valuable an agent as chloroform in our own time.

In conclusion, refraining from a specific description of the requirements of the physician and surgeon, and also from counsel to the students in relation to their present and future careers, as unnecessrry for a body of men distinguished by good citizenship and practical Christianity, obeying the rules of rectitude and unselfishness,—he drew a picture of the laborious and important duties devolving

upon a practitioner of the healing art, in relation to the family, to society, and to the nation, and alluded to the courage, patience, perseverance, intelligence, and skill demanded at their hands. He concluded by observing, that in the vast multitudes of Medical practitioners engaged, not only in this country, but in others, there existed for the benefit of the world a host of active apostles engaged in a mission among men than which none could be grander, nobler, or more nearly approaching to the divine—grand, inasmuch as it rested its labours upon the widest basis of natural knowledge—noble, because it was devoted to the relief of suffering and disease; and almost divine, not merely because it was exercised by virtue of that controlling power, free-will in man, and was marked by the god-like characters of universal help and benevolence, but because it had in the olden time—in the cradle of Christianity—received the sanction of being followed by Him of whom it was expressly recorded that He visited this earth to do His Father's will.

ST. BARTHOLOMEW'S HOSPITAL.

Dr. Andrew spoke to the following effect:—To-day's duty has been performed in this theatre so often and so well, that its difficulties yearly increase. We can but offer our best good wishes for your success, and point out the means by which that success is to be obtained—viz., by work—honest, daily work. Your time as students is too short for you to be able to waste any of it with impunity; but if any of you have already wasted more or less of it, remember that a vigorous effort, a diligent use of the opportunities you enjoy here, may still in part retrieve the past. You are bound to work by many considerations; the serious responsibilities which the practice of our Profession must bring with it, the duty to maintain the ancient fame of our school,—a school in which men like those who have passed away from us this year, Mr. Lawrence and Dr. Kirks, have laboured. You have also to maintain the credit of a noble Profession: to take care that no disgrace fall upon it through the fault of those who profess it. Our Profession is a noble one, and yet there are reasons, some depending on our own fault, which interfere with its proper recognition by the public. Men expect too much from us, and, beginning by demanding impossibilities, end by denying the usefulness of the knowledge which we really do possess.

On our part the claims of our Profession are not always advanced firmly or judiciously; argument on Medical questions is sometimes personal in its tone, and, owing to a vicious system, Medical differences of opinion come out with unpleasant distinctness in courts of law. Practically, also, we do not assert sufficiently the claims of Medicine, as distinct from its ancillary sciences, to an equal rank with other branches of physical research. Now, if the term scientific is applied, whether rightly or wrongly, to such things as chemistry, botany, and ship-building, it cannot fairly be withheld from Medicine. We, no less than those who pursue any other branch of physical inquiry, are engaged in the investigation of law, in the application, for the benefit of mankind, of the knowledge we have gained. The object-matter of our inquiry is not less certain, not less subject to law, than any other; the faculties we must employ, reason, judgment, accurate perception, are the same, and yet the term scientific is denied to us. The fault is partly our own. We misstate the end of our art. Its perfection is to be judged of, not solely by its results, but by the capabilities of the material with which it deals. The endowments of living structures, cannot be altered or modified except within very narrow limits; it is probable that there are diseases which must be always as incurable as old age.

Again, there is often a tendency to make Medicine a mystery; we cannot do that and at the same time claim scientific standing. On the other hand, we are apt to undervalue the knowledge we do possess. Every science rests upon ultimate facts—*i.e.*, facts which have not been explained; but in Medicine we are not content to accept anything unless we can at the same time explain it. But physiological reactions are as certain as chemical ones, in disease not less than in health, and belong to the same order of facts.

Medicine, too, has suffered perhaps more than any other branch of knowledge from imperfect observation and hasty generalisation, while its successful study requires especial accuracy and caution; for we cannot verify and repeat experiments as in other sciences, we cannot trifle with our patients' lives or control the conditions under which we must work, and we may be also wilfully deceived by our patients themselves. The difficulties in our way are so great that we ought rather to wonder at the extent of our knowledge than complain of its incompleteness. But we must remember that knowledge cannot remain stationary; it must advance, or else it will go back and be lost. It is the product of the labour of no single place or generation, but of all. Each must contribute its fair share. Above all, those who enjoy advantages such as ours must be blameable if the progress of our art is retarded by their remissness.

ST. THOMAS'S.

The winter session of the Medical School, in connection with St. Thomas's Hospital, Newington, was inaugurated by an address delivered by Mr. W. M. Ord, M.B., Dean of the Medical and Surgical College. The lecturer took as his motto,—"How best to do the daily work," which, he observed, was the great problem of life. Men and things were estimated and acquired influence and power more and more according to their actual worth and benefit to society; less and less in virtue of any prescriptive claim. This was seen in the position now occupied by the liberal professions as contrasted with that they enjoyed in the beginning of last century. Comparing the doctor and the clergyman of to-day with their predecessors in the pages of Smollet or Fielding, we learned that, not merely men, but classes might, by earnestness in well-doing, raise themselves and acquire power. Their present position was for both these professions the heritage of noble men who had infused the true pastoral spirit into the one, and taught the other to depend not upon tradition and empiricism but upon careful processes of scientific observation and reasoning. If the Medical Profession was to take a higher position than it now occupied it would progress by the same means. If it receded the cause would be that men, thinking they acquired by membership the social position accorded to their body, neglected the sacred duty of work and so fell behind. As the circle of the months placed them again in the portals of the academic year it was fit they should make some survey of the past and its results, to see how far they had done their work well. In that hospital they had every inducement to be careful in self-regard, for they had before them a rare opportunity. The hospital had been removed from the site consecrated for several hundred years to the healing of the sick, and after long casting about for a proper abiding place the administrators of her large resources had enjoyed a full opportunity of carrying out some such self-investigation as he described. Of the results they could in part already judge. Those who had seen the plans of the new hospital would, he thought, agree with him that they declared themselves, even on slight examination, to be the offspring of wide care and thought. Those who knew anything of their history knew with what care all the good and bad points of the old building had been considered; with what industry comparison and inquiry had been instituted with reference to nearly all important hospitals at home and abroad; and with what readiness advice and suggestions had been received from all persons whose opinion appeared to be of value. Without attributing perfection to the proposed new building, one might safely say that it would be as nearly perfect as men conversant for many years with the capabilities of the old hospital, conversant with the requirements of to-day, and adding to experience a thorough survey of all contemporary work of like kind could make it. With regard to the fitting of the buildings, he observed that as in men habits and usages of good origin became prejudicial by lapse of time and change of circumstances, so they might expect to find many points in the administration of an old hospital requiring reformation.

The ways and needs of society changed even within a generation. Powers and offices beneficial at one period were useless, or worse than useless at another; routine tended everywhere to creep in, dragging all things down to one level of unsympathising, unexpansive coldness. If, as there was every reason to believe, their administrators were bent on treating these matters with the same breath and earnestness as they had displayed in regard to the building, they might well wish them good speed in a task of great difficulty and delicacy. The use, however, of a hospital which particularly concerned them at present, was not its direct object in ministering to the sick within its walls, but its secondary use in affording instruction to young men, in order that they might be qualified for the care of the sick outside its walls, and presenting also to men of experience a wide field of observation, whence they might draw fresh knowledge for the advancement of Medical science and the benefit of the sick in all places. The school, which, using the hospital for purposes of illustration and practical instruction, added also theoretic and scientific teaching of its own, had of course to follow the fortunes of the hospital. If the new hospital was good, and the administration orderly, success would follow at once, for there would be offered to the public that for which a demand already existed. Assuredly, however, the public would require that these conditions should be fulfilled according to the pretensions of the place, and success would be permanent only in proportion as the avowed objects were well considered and thoroughly carried out. If the hospital was likely to prove worthy of its generation he firmly believed that the school would not be found lagging. But, the school must needs make its own retrospect, and be resolute both in the search for faults and abuses and their remedy, sweeping aside all mist of prejudice and habit, and looking with clear eye to the necessities of the present. In the latter portion of his address the lecturer delivered some excellent counsels to Medical students on the method to be pursued in their studies, and the personal habits and qualities they ought to cultivate.

LONDON HOSPITAL.

Mr. WALTER RIVINGTON, M.S. and B.A. (University of London), assistant-surgeon to the hospital, delivered the opening address. He said their Medical schools assembled that day under the impulse of a great moral force. At that moment a similar impulse was crowding our streets and marts with the votaries of profit, and before night had far advanced would crowd our theatres and our ball-rooms with the votaries of pleasure, our public-houses with the votaries of gin, and the bitters to follow, our dens of infamy and our houses of shame with the votaries of vice. A similar impulse filled our churches and our prisons; produced indirectly our births, directly many of our deaths, our marriages, our murders, brought them their patients and their fees, answered all their legitimate and illegitimate advertisements, was active at every age, in every condition, in every occupation, and in every clime, had been in operation from the creation of man, and would act until he ceased from the earth. Underlying almost every form of activity, amid every diversity of mind, there was this common bond of union—attraction to some real or fancied good. Now the good which Medical students were attracted directly or indirectly to seek was, in one word, success—success in their studies, success at their examinations, success in their future careers. By success he did not mean mere money, mere position, mere prizes, mere credit, but real improvement here for real usefulness hereafter; and to this ability, labour, and character were passports. Not unfrequently, however, very superior abilities, industry, and integrity secured the major key which unlocked the gates of worldly wealth and favour. If money was to be their chief good, their being's end and aim, their sole test of success, there was slight occasion for trouble or toil. Let them find out what was their pecuniary interest, and then, regardless of opinion and the claims of their professional brethren, take the necessary steps to procure it. A little knowledge, retailed with judgment, and discretely draped in politeness and pretence, would answer all their purpose. Success would the sooner crown their efforts if they stole a few leaves from the time-honoured text-book of quackery. But, before they did this, they should ask themselves calmly what is the real value of money that was not legitimately earned? what the real value of reputation that was not thoroughly deserved? The lecturer then quoted Sir Benjamin Brodie as an example of perseverance achieving a high success without extraordinary powers, impressed on the students the necessity of work for all alike, the duty which devolved on them of discharging truthfully and manfully the debt which they were incurring, and urged them to acquire, if possible, a love for their calling resembling the devoted love for their arts of the painter and of the sculptor, for such a love fulfilled all law. After trusting that they had escaped the misspent drudgery of that long apprenticeship which hands over to striplings the responsibility of pulses before they comprehend the circulation of the blood, and the cure of unknown diseases with predestinated salts, or the negative boon of abstaining from poison, and after giving his opinion as to preliminary acquirement, and recommending matriculation at the University of London, the speaker showed the importance of learning theory and practice together, and keeping the end of all Medical knowledge in view—the treatment and prevention of disease. For this purpose they must work with equal zeal in the college and the hospital. They must steer by the official chart, not to be misled by enthusiastic professors emphasising a favourite science, not neglect central for circumferiential subjects, nor adopt too conclusively a *cui bono* policy. The importance of anatomy was pointed out. No cry was to be raised that they learnt nothing from them till they had asked themselves confidentially if they really had endeavoured to learn and to supply shortcoming by augmented attention. The lecturer next urged the students to attend the out-patients in their first and second years, and gave some advice about their conduct in the wards.

MIDDLESEX.

Dr. JOHN HALL DAVIS delivered the introductory address. He said that if there was one day in the year more important than another as an epoch in the life of a Medical man, and as one giving rise to associations of the deepest interest, it surely was that day on which the various schools of Medicine assembled in their several colleges to inaugurate a new session of Medical studies. It was on that day that the country sent up fresh candidates to fill up the vacancies yearly occasioned in the ranks of the Profession by death or by the infirmities of sickness or of old age, and to meet the increasing demands for Medical aid in our home and colonial possessions. Thus, by the fresh infusion of young life the Profession was renewed and sustained from year to year for the continuance of its high and noble purposes in contributing, under Providence, so importantly to the welfare and happiness of the human race. The Profession on which they were about to enter, that of Medicine, was truly a noble calling, and one which in its rude beginning no doubt sprung out of a natural desire implanted in man as an instinct to relieve the pain and suffering of his fellow creatures, and therefore almost as ancient as the creation of man, but as a distinct Profession founded by Hippocrates, the Father of Physic, more than 2,000 years ago. Since that remote period, however, through succeeding generations up to the present time, the power of Medical science and art, curative and preventive of disease, had, under the blessing of Divine Providence, been wonderfully extended by the intellect and persevering industry of man, and more remarkably so through the developments and valuable applications of science during the last 300 years. As an instance of an important accession to Medical knowledge within that period, he might mention the discovery, in 1628, by the illustrious Harvey, of the circulation of the blood, a discovery which might with perfect truth be said to have

effected a complete revolution in Medical science. Another remarkable discovery, which formed an important era in Medicine, since it had been the means of conferring a blessing on the human race, was that of vaccination by the immortal Jenner. The lecturer adverted to the discoveries of Hunter, Cuvier, Laennec, and other great lights who had adorned the Profession, and condemned the prize system which prevailed in some schools. He then proceeded to urge that the Government of this country should reflect on the value of Medical services to the welfare of the army and navy. If they would secure for these two powers the most efficient Medical skill, the Ministers and other authorities in these departments should hasten to redress grievances, which, by deterring the best men, as a rule, from entering them, could not but act most prejudicially to the interests of those services. The regulations complained of as affecting the Medical officers of the army were principally as follows :—1. The important gift of precedence according to the relative rank of the Medical officers and the advantages attaching to the rank with which it corresponds does not exist with regard to Medical officers presiding at mixed boards. It was ordered by the Royal Warrant of 1863 that relative rank shall not entitle the Medical officers to military command of any kind, nor to the presidency of courts-martial, courts of inquiry, committees, boards of survey; but when the presidents of such courts, committees, or boards shall be junior to the officer of the civil department, then such member of the civil department shall attend as a witness, but not as a member. The Medical officers feel that this non-recognition of the privileges which their rank should give them seriously prejudices their position in the army; and that it is detrimental to the interests of the service is manifest, said the lecturer, from the following consideration :—The results of excluding Medical officers from presiding at mixed boards is this—that the senior Medical officer, the man of experience, is distinctly excluded from sitting as a member at all those boards at which food, clothes, water supply, quarters, and ventilation, are subjects of investigation. The senior Medical officer is, in fact, excluded from sitting at the board unless there happen to be a combatant officer senior to him in rank, a circumstance of rare occurrence. The position of the Medical officer at mess is ambiguous and often a very painful one. It does not depend upon the relative rank, but upon the will of the commanding officers, and consequently differs in various regiments. Some commanding officers permit Medical men to hold their position at mess according to relative rank, other commanding officers refuse to do so. It is inconsistent with the warrant of 1858 that the names of the Medical officers should not appear in the Army List, while the report of the Royal Commissioners of 1857 says that Medical officers' names should appear according to their rank. By the Queen's regulations of 1859, Medical officers were removed from the regimental staff to the civil department, although they belong to the regimental staff by every definition of the terms. They wear regimental uniform, they have special regimental commissions, for which they pay; they subscribe to mess and band. One result of placing them in the civil department was that Medical officers for a time were deprived of funeral military honours. These, however, were restored by special order, but can even now be denied by commanding officers who may choose to follow strictly the Queen's regulations. With regard to the position of Medical officers in the navy, the lecturer quoted from a pamphlet published by Dr. F. G. Brown, Consulting Surgeon to St. Bartholomew's Hospital at Rochester. He (the lecturer) was permitted to state that at a meeting of the Royal College of Physicians, held on the 6th of June, it was resolved that the president and censors of the college should act as a committee to consider the best mode of using the influence of the college to induce the War office and the Admiralty to improve the position of the Medical officers of the army and navy; and, further, that, on the 26th of June, the letter prepared by the president and censors was submitted and approved by the college, and subsequently forwarded to the Minister of War and the First Lord of the Admiralty. The lecturer concluded with some advice to the student, mainly in reference to the study of comparative anatomy, pathology, botany, and kindred sciences.

WESTMINSTER HOSPITAL.

Introductory Lecture by Mr. Barnard Holt, Senior Surgeon to the Hospital.

The session was inaugurated with an introductory address by Mr. Holt, who inculcated the absolute necessity of a sound preliminary education to enable the student not only to appreciate that which he has to learn but to fit him for the position which every member of the Medical Profession may hope to attain. Mr. Holt said, "although I am desirous of avoiding the topics that have been so ably handled in former years by my predecessors, yet it is impossible not to follow in some degree in the same track. It is necessary to recommend the same great moral principles,—love of truth, active benevolence, untiring industry, and a desire for the acquisition of knowledge, which form the basis of professional excellence. In a highly educated assembly like the present, everyone has imbibed notions more or less distinct of his moral duties, probably some taste for literature, and perhaps some feeling for art. These acquirements, however, go but a little way towards the accomplishment of that moral and intellectual training, which is a necessary element of the Medical character, and which has won for our Profession its present social elevation. Even the fortunate possessor of the most comprehensive preliminary education will find that he has much to effectuate by his own industry. There is an education derived from self discipline and reflection, that no school can bestow. The more cultivated the mind of the practitioner, the more his intellect is sharpened by rationalistic exercises, the more his moral perceptions are developed by a vigilant conscientiousness, the more his nature is softened by an indulgence in the refined pleasures of taste, so much the more efficient will he be in the practice of his art, the greater will be his perspicuity in discriminating nice shades of disease, the richer will be his invention of resources, the more persevering his zeal for the welfare of his patient, and, above all, the more liberal and just will his bearing be towards his professional brethren, whom his enlightened understanding will have taught him to regard not as rivals, but as colleagues and allies, in the great crusade against pain, disease, or death."

Mr. Holt then alluded to the student's reasons for selecting the Medical Profession and impressed upon them the necessity of exerting themselves to the utmost and losing no opportunity of gaining practical knowledge by attendance in the wards. "You are about to enter our Profession, a profession which to practise it as it should be practised will sorely try your self-denial, yet a profession of the highest honour, a profession of the most sacred trust. Do you enter it for emolument, for fame, or with the desire of doing good, or I might add in order to combine a competency with the high feeling of the benefits which by a severe course of study, you may confer on your fellow creatures? I am afraid as a general rule these inquiries are never made; it is a very difficult thing in the lottery of life to bring the young mind to consider seriously all the bearings of the profession he selects. It may be that you enter our Profession because your father is already a worthy member of it, it may be that your parents desire to provide for you a competency which you may obtain by the exercise of our honourable Profession; but whether it be one or whether it be the other, let me beg of you that you will avail yourselves of every opportunity to become proficient. If time allowed me I would direct your attention to the nature of our separate faculties and the astonishing results of their combined actions; I would try to show you how they antagonize one another, and that the victory of good over bad qualities, or bad over good depends upon your own principles and determinations; that you have a controlling energy by which you can array your mental powers and prepare them for the contests in which success is glorious."

The Lecturer then remarked upon the indivisibility of

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 11, 1865.

THE 'TIMES' ON THE ART AND SCIENCE OF MEDICINE.

At the very period of the year when the introductory addresses delivered at the different Medical schools, and reported in the daily journals, are making the public in some degree acquainted with the aim and scope of Medical science and practice, the principal morning paper of Oct. 3 takes the opportunity of sending forth a leading article, intended to depreciate our Profession in general estimation, but exhibiting only the malevolence, and, at the same time, the ignorance of the writer. The publication, however, of such an article is quite in keeping with the tactics of the 'Times,' which, while refusing insertion to communications from learned and distinguished members of our body, fills its columns with stories about curing cholera by the use of salts, and abolishing the cattle-disease by the administration to the animals of decillionths of a grain of "arsenicum."

The article begins by stating that there is probably no profession which, in its aggregate or corporate capacity, excites so little the interest of the public as the Medical, and that it has no strong hold on the extra-Medical classes like the Church or the Bar. Now, we venture to assert that the very reverse is the case, unless the "extra-Medical classes" are confined to the members of the Church and the Bar themselves, and to those comparatively few persons in the terrestrial globe who are personally concerned in the interests of either. The Church, at the best, constitutes only a limited society in Great Britain and her dependencies, and Law, as is well known, is a luxury or a curse, as the case may be, to the rich or well-to-do classes; but the domain of Medicine is circumscribed only by the limits of the globe itself, and its beneficent operations extend to all mankind. The poor, the sick, and the destitute, with whom Law never concerns itself, constitute a great and important portion of the recipients of Medical succour; and the Jew, the Mahomedan, the Hindoo, or even the savage, who either repudiate the doctrines of the Church, or have never come within its influence, are all, at some period or other, the objects of the physician's or the surgeon's care. If the writer of the article meant that Medicine does not offer to the aristocratic classes so many sinecures as the Church, or that it does not grasp so many lucrative appointments as the Bar, he was right enough; but this view of the case is rather creditable than otherwise to the members of the Medical Profession, who, with little to look forward to in the way of riches and honours, devote their lives and their health to the task of assuaging, as far as lies in their power, the sufferings of their fellow-creatures.

But the article goes on to allege that the Medical Profession regulates its affairs with very little reference to any opinion but its own, and "keeps on its course without being turned aside to the right or the left by deference to *popular clamour* or unprofessional opinion." Perhaps this expression ought rather to be regarded as a compliment than otherwise, and if the Church and the Bar are influenced in their course (as the writer seems to suggest by the antithesis he proposes) by "popular clamour" it is well that the Medical Profession turns a deaf ear to any such tumultuous expression of public opinion. But if the writer means that Medicine pursues some long-beaten but obsolete track, which other professions and pursuits have learned to avoid, and that it refuses to travel by some more expeditious road than that which was trodden by our forefathers, he is entirely mistaken, and displays his utter ignorance of the whole history of Medicine during the last five hundred years, and of its position and prospects at the present day. As well might he have asserted, taking his favourite illustrations from the Church and the Bar, that modern Divinity consisted of a collection of aphorisms from the writings of Confucius, or the mysteries of Egyptian mythology, or that our present legal code was the same as that of Lycurgus or of Numa Pompilius. Absurd as either proposition would be, it is equalled in absurdity by the language of the article to which we refer, where we are told that Medicine is not a practical science but (we quote the exact words) "*a secret and traditional mystery* deposited in the hands of a few persons, and neither to be touched, handled, nor discussed, except by its initiated and privileged professors. Hence," this sagacious expositor of Medical error goes on to state, "the establishment of a canon of orthodoxy quite as rigorous and exclusive as any that has ever been established by the strictest theological dogmatist. But," he warns us, "the days are coming when this position will become untenable."

If it were worth while to argue with a writer who is obviously so entirely unacquainted with the subject on which he professes to enlighten the public, we might inform him that "the canons of orthodoxy" to which he refers have no existence except in his own brain, and that the "secret and traditional mystery" of Medicine must be hidden somewhere in the same quarter, for as to ourselves, we confess that this is the first time we ever heard of it. But it is very likely, in the jumble of ideas thrown out in this curious article, that the writer is confounding quackery with legitimate Medicine, and that the condemnation due to the former is made, by a strange inversion of logic, to apply to the latter. It is quite true that certain species of quackery *do* consist of a series of canons of supposed orthodoxy, or of certain assumed secret and traditional mysteries. The composition of Holloway's pills, for instance, is a secret, and we are positively assured that they cure all diseases. Here, if you will, is a mystery, namely, the manufacture of the pills. "Holloway's pills cure all diseases;" here is dogmatism, expressed in terse and emphatic language. Morison's pills are equally mysterious, equally efficacious, and they are also traditional, because we believe that Morison (notwithstanding his pills) is dead, and the mystery, together with the profits, has descended to his posterity or his executors. So, again, the homœ-

pathic quackery consists essentially of certain supposed canons of orthodoxy, such as the famous *similia similibus curantur*, and the dogma that the efficacy of a medicine is in the inverse proportion to the dose in which it is given. The first of these propositions is unsupported by facts, and the second is inconsistent with the laws of Nature, and it must have been to some such absurd and groundless fancies to which the 'Times' unwittingly refers, when it ridicules the use of mere words, "and all sorts of vague metaphorical terms, which are little better than ingenious contrivances for the concealment of learned ignorance."

As we have before remarked, it would be a mere waste of time to argue with a writer so hopelessly ignorant of his subject, and we can only advise the 'Times,' which has a circulation quite sufficient to enable it to pay competent contributors, either to employ, when treating on Medical subjects, some persons who have at least "crammed" a few of the elements of Medicine, or to let the matter alone altogether. A writer who speaks of the "morbid pathology" of the human body (as in the article referred to), shows not only his unacquaintance with Medical terms, but his deficiency in the rudiments of common etymology, and it would be hopeless, in his present nebulous condition, to try to illuminate his understanding. In mere compassion to his benighted state, however, we advise him to consult a dictionary before he makes use of words of which he does not understand the meaning, and we may repeat that canons of orthodoxy and secret and traditional mysteries, if they ever existed in Medicine, have been banished since the dark ages, and that if they reappear in the present day it is only in the arrogant pretensions of quackery, which, indeed, assumes to do what no honest Medical man professes to accomplish, namely, to find an infallible clue to the nature of disease, and to announce a specific remedy for every human or epizootic malady.

Since the above was in type, it has transpired that Mr. Delane, the Editor of the 'Times,' was out of town when the article on which we have commented was written and published, and his place was probably supplied by some understrapper who has yet to learn his business. Independently of the feelings of indignation and contempt which the article will excite throughout the Medical Profession, it is disgraceful to the 'Times' that so illiterate and incompetent a writer as this would-be critic of the science of Medicine should be allowed to parade his folly before the public in the pages of a journal which, at all events, has a reputation of being conducted with ability.

MEDICAL REGISTRATION BY STUDENTS.

The Medical Council has issued a notice that all first years' Medical students in the present year are to register their names at the office of the Branch Registrar, and it is also announced that this registration supersedes the necessity of registration at the register offices of the different Medical Corporations. Such is the fact; and we have the best authority for stating that registration at the College of Surgeons and at Apothecaries' Hall, although still carried on by those bodies, is no longer necessary except in the case of second and third years' students.

GENERAL CORRESPONDENCE.

To the Editor of the Medical Circular.

Dear Mr. Editor,—What has become of Vigilans? The last information your readers had of him came from himself. To their great regret he announced his departure for the Rhine, or Switzerland, or both. Let us hope he has not tumbled down a crevasse in an alpine ascent, or become a denizen of the Rhine Gods, in their crystal caverns at the bottom of the Rhine. We cannot afford to lose so good-humoured, well-intentioned a satirist, and although we may rejoice at any attempt by your contemporary the 'Lancet,' to rival him, we would rather have back the original. Lately, in the 'Lancet,' appeared a very good essay in the right direction, but it fails at the very point where Vigilans would have made his indelible mark. It deals out excellent advice, and I hope you will not object to quote it entire, leaving it for Vigilans to renew the topic on his return. Your constant reader,

F. T.

P.S.—Let me take the opportunity of thanking Cyclops for his very suggestive letters on physiology, which I read with great pleasure.

AUTHORS BEWARE!

As September comes round, the Medical publishers are, to use their own words, "preparing their autumnal lists of announcements of new works," and we, therefore, venture to address a word of warning to intending authors on the titles of their *magna opera*. The fashion has unfortunately come in (and the sooner it goes out the better) of giving "taking titles" to Medical works, with, it is to be feared, the view of catching the eye of the non-medical public. Just now there seems to be an idea that the public has an objection to "cutting operations," and that it is a "good card" to bring out a book on the cure of every disease under the sun "without cutting." Thus we have had for some time a work on orthopædics "without cutting tendons;" we have more recently a work on the treatment of tonsils "without the operation of excision," and we are threatened with a work on squint and its cure "without operation."

Another phase of self-laudation has also "cropped out," in the way in which go-a-head authors of the present day are not content to announce simply a book on the diseases of a given organ and their treatment. Nothing under the "cure" of the given disorder is now sufficient, or, at least, the treatment is announced as the "successful treatment," though we have no great faith in the permanency of such cures, or the success of treatment which requires constant advertising and yet does not get into common use.

Let us, in the interest of our common profession, and to assist young authors in retaining their self-respect, earnestly beg them to beware of these errors, which, if persisted in, will not fail to recoil upon their own heads at a later day. No man ever yet pushed his way into the first rank of the profession or of practice by diligently puffing a little half-crown book on any subject,—be the title ever so taking, or the treatment proposed ever so successful and captivating. A few patients may be caught and a few fees pocketed, but the "successful" author's mark is irrevocably made with the profession, and no man, however self-confident, can afford to disregard the feeling of the profession at large.

The Seamen's Hospital.—The Seamen's Hospital Society has recently received from Mr. De Berg, the Russian Consul-General in London, the sum of 131*l.* 8s 8d., being the amount of contributions from the Governments of several provinces of the Grand Duchy of Finland, and collections from Finnish merchants and captains in aid of the fund for the reconstruction of the hospital, so long established afloat off Greenwich. The Grand Duchy of Finland has also, by consent of the Emperor of Russia, forwarded to the same society the sum of 20*l.* as an annual subscription to the hospital, with a courteous acknowledgment from Mr. De Berg, the Consul, of the care and attention received in the *Dreadnought* annually by a large number of Finnish sailors.

WESTMINSTER HOSPITAL.

(Continued from page 259.)

Medicine and surgery which he regarded as one science, and after giving a brief history of the progress of surgery alluded pointedly to the present state of the profession and the inclination of the public mind to specialities and special hospitals, which he severely criticised and said that although medicine and surgery were essentially one science, the great division into Physic and Surgery is not without its advantage; that although it in no manner absolves the Physician or Surgeon from becoming acquainted with all the details that appertain to a thorough knowledge of his profession, yet it enables him to accumulate a larger experience in the branch he selects than if he practised generally. The surgeon in general practice has but little opportunity for that deep reading and contemplation so necessary for him who is desirous of occupying the highest rank.

It is impossible among the multiplicity of his engagements both by day and by night that he can so familiarize himself with all the improvements in medicine and surgery as to be capable of forming the best opinion and in many instances the refined, so to speak, diagnosis, which in intricate and difficult cases is to turn the scale to health or death.

This Mr. Holt said was well known by the gentlemen to whom he referred and although they might be highly educated and have a large experience which was available for all ordinary occasions, yet they cheerfully availed themselves of the opportunities of consultation, whereby they not only benefited their patients, but themselves became familiar with the more extended experience of their fellow labourers.

The Lecturer then dilated upon the necessity of a thorough knowledge of Anatomy and Physiology as the basis of all sound professional principles, and inculcated the necessity of clinical study as superior to systematic lectures. The book of nature was the book for study and by it and it alone could the practitioner be successful. In conclusion Mr. Holt said, "I have thus faintly endeavoured gentlemen, to impress upon your minds the indubitable fact that in choosing the Medical profession you have entered upon a career in which all the good and great qualities of human nature are called forth. I have also shown you the way by which this desirable object can be reached. Industry and perseverance are necessary to success in every line of life, but most especially so in the attainment and practice of a noble art, which puts to the proof the rarest of the human virtues and has occupied the thoughts of some of the most gifted of our race. Our profession is indeed a noble calling, in every branch it affords occasions of self sacrifice, and demands the exercise of the highest powers. The physician by his varied learning, the surgeon by his disciplined skill and fortitude, and the general practitioner in his wide field of usefulness, if he fail in the achievement of fame, which is but the lot of few, he is sure by the conscientious discharge of his duties, not merely to win the hearty respect of his species, but to command that perfect self contentment which is the constant attendant of an approving conscience, and the very core and essence of happiness, here and hereafter."

After the lecture the Medical officers and lecturers received the students and their friends at a conversazione in the board-room of the Westminster Hospital, where numerous objects of interest were collected and refreshments were served.

ST. MARY'S, PADDINGTON.

The introductory address at St. Mary's Hospital was delivered by Dr. HANDFIELD JONES, F.R.S., one of the lecturers on Medicine. After the usual greeting to the older students and friends of the school, he commended to the students the choice of a profession which they had made, on the ground that it afforded them no mean opportunity of serving God and bettering their fellows. Though it afforded them none of the high prizes which were to be won in other callings, it brought them into pleasant and friendly relations with many who were most worthy of their esteem and regard, and that in itself was no small advantage. To do good work, and to be loved for doing it, was surely an enviable lot, and this was in the reach of all who practised their profession intelligently and faithfully. The true physician should seek his eminence, not so much in outward distinctions as in attaining increased power and mastery over disease. For the promotion of this great object combined effort on the part of the profession was strongly advocated. Quackery, he believed, could never be suppressed by any legislative interference, and he did not think it was worth seeking for. Even among our French neighbours quackery flourished in spite of prohibitions and fines. An instance was related, showing that even high attainments in physical science are no preventitive against the reception of patent absurdities by the mind, which, though fully aware of their falsehood, cherished them nevertheless. The extraordinary influence of certain mental states over the body was next adverted to, and some remarkable instances were cited, both of the prevention or repression of disease by cheerful excitement and of the apparently curative powers imparted to insignificant remedial means by strong feelings of hope and faith. It was notorious that constipation, which had required on former occasions the strongest drugs, had yielded in a much shorter space of time to bread pills, while the patient believed he was taking some very powerful remedy. It was of great importance to the student to be well aware of these facts and to see their bearing upon the treatment of disease as well as upon many instances of the apparent success of means which every rational person must believe to be totally without physical agency. In connection with this subject, the lecturer took occcasion to state plainly the real ground why the Medical Profession refused to have anything to do with homœopathy, or to meet its practitioners in consultation. It was not that the doctrine of *similia similibus* was the real obstacle; this, if it were, might be held, as many other queer notions had been held in men's minds, and prove no hindrance to their co-operating with their fellows on matters of mutual concernment. But when a Medical man believes that the weaker a medicine was made the sharper was its effects, or that billionths of common salt, salica, or sulphur, could exercise curative virtues, though we take in our daily food much larger quantities of the same substances every day, he puts himself really out of the power of a man of ordinary calibre of mind to consult with him. They might as well call two engineers to act together in building a bridge, one of whom believed that the thinner and weaker the supporting structures were made the greater would be their power of resistance during strain. It was no intolerance or prejudice, but common honesty, that compelled rational practitioners to decline meeting those who entertained these peculiar views. Were they to do so they must feel that, according to their own principles, they were acting as charlatans. The charge of bigotry or unwillingness to receive improvements in Medicine was most completely refuted by the ready way in which the profession had advocated sanitary improvements to their own unquestionable disadvantage. The next subject touched upon was the question how far diseases could be regarded as sufficiently constant, and regular processes to make it possible to determine what was called their natural history—that was, to ascertain what course they would pursue in the great majority of cases if left entirely to themselves, without any Medical treatment whatever. The lecturer remarked that it was difficult in many cases to distinguish between the original morbid action and the complications to which it gave rise; that the duration of diseases of the same kind depended in some considerable measure on their gravity—that was on the degree in which the system is affected by the morbid influence, and that they were modified also materially in their course by constitution and diathesis and the prevalent epidemic influences. Diseases by their outward show might be very much the same, might have the same names, and be counted in the register as identical, and yet in their tendencies and ...

al nature might be most different. This was completely cognised by the best authorities, and yet was far too little nsidered in discussions on the treatment of disease.

CHARING-CROSS HOSPITAL.

The Introductory Address was delivered by Dr. Chowne, .R.C.P., who commenced by remarking that in the choice a profession, and in considering and comparing the eculiar circumstances which may recommend the Church, e Law, or Physic, or, indeed, any other profession, though scarcely anything can be of greater importance an the mental preference of the student, which, for the ost part, carries a mental aptitude along with it, the dent mind might fulfil a determination to succeed, and the sence of a strong early predilection must not be regarded an insuperable stumbling-block. To the votaries of edical science there are many inducements, although in way of riches, titles, or fame, in the ordinary sense of latter word, they are but few. Of the Physician, indeed, noiseless and "even tenour of his way" is amongst his hest perfections; and both his path through life and his e are rather of a kind to make him happy than either althy or great.

The doctor proceeded to say that it might be useful to ress some suggestions of a precautionary nature to those are either now commencing their ascent of that Mont nc of the Medical student—the Medical curriculum—or hose who have already climbed to the first, or even to second, of those resting places, in Alpine parlance, ed "châlets," but which are in the academic language ed vacations, and are now braced up for another march. would venture to forewarn the students who are new to r forthcoming work, and to remind those who are not, courage and industry, and constant vigilance against aps will be necessary. The mention of mishaps almost e same breath with the mention of Mont Blanc might l to the mind that the avalanche which always threatens sometimes, though happily not often, work harm to wayfarer. The great danger to the student, however, om minor but more common accidents and incidents, small trips, and stumbles, and digressions, which he can d if he will, than from events beyond the reach of a onable forecast to foresee or of reasonable efforts to away from. There will be no giant or really great ulties otherwise than as they may be measured by re- e efforts to overcome them. Every student who has to the Medical curriculum should at once make himself ainted with his real position and what he has to do. osition is that there is hard work before him; that he lf must do it, and that his time is limited: that time ide wait for no man; that the earth will turn upon its and that the sun will go down at its appointed minute, ill not be a laggard to suit the convenience even of ost excusable of idlers; that when the night comes ay is irretrievably gone. Some will have used it; will have wasted, and must abide by the loss. Every ost leaves a blank on the mental tablet, which will tell and impeach the delinquent when the time arrives for g what has and what has not been committed to it. application to study should have as few breaks as ble, consistently with health. The profit will be the er the fewer the interruptions.

ne call anything that approaches to long hours of study y. Be it so; it is, nevertheless, the very kind of y by which the first men in the state become first men, ich the highest places of authority are won, and by distinction and eminence, and elevation to the sum- f the most honourable aspirations and ambitions are ed. Some recreation the student must have, but it l not, during his working time (the session), go a step d a needful rest for his mind, and it should be such as the same time conduce to his health. When the stu- an take notes well, he should do so; they help to com- memory what might otherwise be lost, and they give to after-reading. In reference to attending "Hospital ce," both in the wards and in the out-patients' depart- ment, Dr. Chowne stated that there is much which the student should see and carefully observe as well as hear; tha by long and constant observing, the eye acquires a knowledge and insight into certain visible peculiarities, called the "physiognomy of disease," which language cannot impart, but must be learned by the eye, and is inexpressibly valuable.

The first step in dealing with disease, "diagnosis," or recognition of the nature of the disease, seems at first sight like a mere colloquial affair of questions and answers. We human doctors, as we are called, in contradistinction to veterinary doctors, have great advantages; and who can guess what our veterinarian brother would sometimes give to get a word or two from his patient, or how sincerely he would rejoice "when first the creature found a tongue?"

The attention of the students was forcibly directed to noticing certain associations of certain forms of mental aberration with certain forms of bodily disease, of which the Doctor gave several examples—an extremely interesting subject, on which the late Sir Henry Halford read a very valuable essay before the Royal College of Physicians in 1831.

The value of Medical science in connection with Medical jurisprudence was expressly alluded to, and the danger anxiously pointed out of evil designs on life being perpetrated where illness already exists, and might tempt the ignorant to speculate on impunity.

In regard to the students keeping records of cases or of any other matters connected with his Medical studies, the value of new facts over that of new theories was especially commended; a fact abides, a theory is often but a fleeting, though a dazzling and a pleasing, sunbeam. Facts, however, whether old or new, require more care in the recording than they generally receive. It is not sufficient that the writer can understand what he has written, or that a cursory reader fancies he understands it,—it should not admit of being misunderstood, or even misinterpreted. Hundreds of records of facts are so weakly worded, so destitute of perspicuity, and of clear and exact definition, as not to be worth a jot—mere verbiage, and little better than a *quasi* learned dust of words, but without an atom of gold-dust, to say nothing of nuggets, however infinitesimally small. It is extremely disappointing when searching, volume after volume, for facts, that when found, one after another, they will not bear the most gentle handling—even for friendly examination, but go to pieces at once, like an old bone in a catacomb. It is desirable that the student should habituate himself to exactness where it is possible, although Medicine is not one of the exact sciences. The real worth of a recorded fact is its strength when opposed to a counter-fact; as the real worth of a witness is his strength when opposed to a counter-witness.

Subjects having sanitary aims will more than ever lie in the Medical student's path; and perhaps there is not a set of young men in the world, just starting to acquire a profession by which they are to earn their living, who would set to work more heartily to strike at what would seem to be the very root of their means of doing so. Down with disease is the standard philosophy of the Medical man—and a very much to be admired philosophy it is, notwithstanding the suicidal look of it; nor can we be surprised that it is popular out of the Medical Profession. It is not doubted that the whole body of Medical men in these dominions hail with gratification every new fact having a sanitary application, and every new method by which such new facts can be obtained.

We can all remember when the balloon was regarded, both metaphorically and in fact, as a mere bubble and a toy —a large bubble and a large toy certainly, but a toy it was considered; it is now an instrument of science—a substantial agent of confirmed utility. Heretofore, the explorations effected by human genius, as regards the sphere which we inhabit, have been restricted to the earth, and the sea, and to certain limited strata of the atmosphere. The earth is delved, and yields up testimonials the most astounding; the sea is fathomed, and the secrets of its depths become comparatively familiar, but the atmospheric ocean in which we

are immersed has been a region inaccessible to the personal experience of the philosopher, except so far as terra firma could conduct the steps of the celebrated Saussure, for example, and other naturalists. The fact is an interesting one, that he (Saussure) about a century ago (1768) made a journey from his native city (Geneva) to Lyons to see the aërostatic machine of Montgolfier. Fain would one know the thoughts which that machine inspired in his enthusiastic and contemplative mind. It may perhaps be assumed, however, that a reflection of those thoughts exists in the conceptions and the scientific aërial excursions of the present day. We see in the enterprising researches of Mr. Glaisher a new era. His zealous and adventurous explorations have already shed new light on some subjects highly interesting to meteorology, and can scarcely fail to raise a hope that they may lead to further knowledge that will be useful to the science of Medicine.

Another subject of deep interest will require the student's attention in connection with diseases of uncertain origin called hereditary, existing in the living himself and genealogically transmissible, although not always transmitted; a study requiring the utmost caution against false conclusions. The laws of the animal economy in relation to hereditary succession of constitutional peculiarities are not sufficiently known to trace the influences which continue or divert, as the case might be, the course of such peculiarities, however certain and even visible their existence. Caprice, as mere caprice, cannot be deemed to have any being in this beautifully organised and beautifully governed creation. Peculiarities of form or surplusage, or deficiency of parts, may appear and disappear for several generations and be thoughtlessly called caprice because it is not comprehensible. But what finger can point at any fiat throughout the whole economy of this marvellous creation that is not incomprehensible? The difficulty of the subject is necessarily increased by the multiplicity of diatheses and combinations of diatheses which are mingled in the veins of every individual; and the importance of it is constantly increasing as a consequence of discoveries, real or supposed, which are constantly in progress. The subject is too difficult and too elaborate for the student to undertake as a whole, and his attention is directed rather to such facts as he may observe while in his actual pupilage, and to the elementary stages of it, reserving the deeper studies and reflections for a future period.

This address was concluded by some remarks on the advantages conferred by Medical societies, and by adverting to the satisfactory progress of the "Junior Medical Society of London."

ALBERT VETERINARY COLLEGE.

On Monday a new Veterinary College in London, having the above title and springing out of one formed in Edinburgh a few years since, was formally opened at a branch establishment in the Queen's road, Bayswater. The head college will, when completed, be situated in Chelsea, but as no fur advance has yet been made towards the erection of the structure there than the purchase of the ground on which it is to stand from the Commissioners of Chelsea Hospital, the company, who are the promoters of the new college under the Limited Liability Act, deemed it wise at once, while public attention is forcibly drawn by the prevailing cattle plague to the importance of veterinary knowledge, to inaugurate their new institution in the branch establishment at Bayswater.

Professor Gamgee delivered the inaugural address. After adverting to what he conceived to have been hitherto the cause of failure in teaching veterinary science, he observed that one of the first points he turned his attention to in Scotland was the prevalence of intestinal disorders among horses, and having collected reliable statistics to prove that of the animals used by agriculturists nearly sixty died of colic out of every 100 that died of disease, he wrote and spoke on the so-called boiled meat system, feeding horses as we should omnivorous pigs, and pointed out the killing influence of draughts of turpentine, oil, and opium. He had drawn attention to the evils attendant on an importation of live stock without adopting proper precautions against the spread of disease, and had advocated the establishment of foreign stock markets and a rigid inspection of markets and fairs. After many years' efforts and steady investigation he thought it rather hard that the Profession to which he belonged should be denounced as ignorant and inadequate for the occasion. There was, in his opinion, great reason for regret that Professor Simonds, who perceived the cattle disease early in June, and the Government who issued an Order in Council on the 24th of July, did not adequately warn the farmers of the appearance of the disease. Acting under the advice of Professor Simonds, the Government said, full five weeks after the malady broke out in London, "that a contagious or infectious disorder, of which the nature is at present uncertain, has lately appeared and now prevails among cattle within the metropolis and the neighbourhood thereof." On the 29th of July he arrived in London, and on the 31st addressed a meeting at the Marylebone Institution on the subject of the strange disease. Thanks to the public press, it was at once known throughout the length and breadth of the land that the cattle plague was in the country, and farmers were put on their guard as to the purchases they might make. This alone saved many a man, he believed, from serious loss, and it was much to be regretted that the alarm was not given one month sooner. With regard to many associations formed for the insurance of cattle he stated that they were working most unsatisfactorily, and he thought that if the Government could be guided so as to benefit by the opportunity, a system could be formed which would add to the public revenue, materially protect the farmers, and enable them to lull the plague. An indemnity fund from the national purse was not required, but there might be a national cattle insurance system, in which every farmer would have confidence, and which in time would realize enough to defray the expense necessary for the supervision of a national disease—a preventive system, affording substantial security to the farmer and his landlord, and helping at the same time to melt down the National Debt. Many people were impressed with the idea that the malady could be cured, but the cattle plague was more deadly and infectious than any other known disease affecting men or animals. Keeping stock in it implied favouring the extension of the disease, and no fact had ever been better established than that you must treat herds affected with this disease as you would glanders in horses. Much as the opinion might jar upon the feelings of those who believed that God has granted a remedy for every disease, he asserted that severe cases of the Russian plague must ever be incurable. He referred to this subject for the purpose of showing that veterinary science was of the highest importance to any country; and, in conclusion, he begged to press on all the claims of the new institution which he held to be the only one of its kind calculated to train men for the real object they should have in view.

"CYCLOPS'" TWENTY-SECOND LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—Dr. Radcliffe says, "Not a few persons still look upon purgatives as necessaries of life;" "they seem to think that the bowels would never act without the customary pill or potion." This maxim has almost become a creed with many, and having been encouraged by the Faculty, the one cannot be called more ignorant than the other. I do not wonder if "they stare incredulously" if they are told that constipation is the natural result of some error of diet." I should do the same, for I ask, what is this "error?" Bowels habitually constipated with advantage in some persons may require very opposite Medical treatment; for what would suit one would not suit another. It then resolves itself into the treatment of each case according to its idiosyncrasy, and each case must always have its physician of the same way of thinking as Dr Radcliffe, and the whole process gone through of dieting to suit

out what agrees and what does not, in order to get these obstinate bowels into some degree of regularity by diet and not physic. Now all this involves such a cumbrous machinery with all its delicate processes, with the doctor always at hand, at a certain expense which everybody cannot afford. Besides, the rectification of some of Nature's doings would seem to imply that life was scarcely worth having if all this trouble was necessary to produce what is called a certain amount of health in the individual. On the one hand, there would be many things which the individual would like which he would be forbidden to take, and many things ordered him which he would not either relish or like; so that, in one way or other, he would really be like our old friend, Sancho Panza. Again, I never knew a dietician a healthy person: first, because he seldom repairs according to his waste; and, secondly, debars himself from certain things which would, perhaps, in their ultimate reduction, produce valuable elements in his system, and just what the system required. Therefore it is not at all consonant to Nature's laws that dieting is the rational plan of treatment, because I will show hereafter that constipation depends more on the value of the fæces than the food, and that it does not much matter what food is taken as long as plenty of fæces is the result. On the other hand, taking Dr. Radcliffe's second proposition, that "constipation is in some cases rather to be encouraged than to be corrected," shows at least an effort of an observing mind to grasp a reason even if it fails to show a true cause. "Man," he says, "is an omnivorous animal; originally it was not so." Now this is quite gratuitous, for it seems to imply that man, in his original state, was a superior life-guardsman sort of fellow, handsome and well-formed in body and mind, ready made from the earth to give laws to the universe and names to everything, and his wife, as beautiful as anything that Belgravia ever turned out on a bridal morning, barring the "leather and prunello," both of whom were presumed to live on the best of fruits and vegetables. For my own part, my ideas of the first man set upon the earth (as only the Creator himself knows) must have been like any other savage we even now see in uncivilised countries, and that he, in his human and omnivorous nature, preferred the killing of animals to support his peculiar organisation rather than be content to live on vegetables. It seems to me derogatory to science, as well as to that mind which Providence himself gave man, in order that he should be above all other animals, and which, in all ages, man himself has so cultivated as to understand the great laws and the wonders of the creation; for, in this fact alone, herbs and seeds might mean meat and food in the general acceptation of the term, and to include flesh and therefore herbs along with the fresh-killed animals, was no doubt the fact of the matter, as everything that was made was made subject to man's necessities. It is well known that all savages are necessarily hunters, and require larger tracks in proportion to live upon than those who afterwards emerge from that state and become agriculturists and storers of grain. Man is the same animal now as he was at first, and no doubt got his "*meat*," as savages do now, wherever he could on the face of the earth, according to the physiological laws implanted in him by his Maker. Dr. Radcliffe introduces the question of eating "too much animal food and too little green meat," and the consequence on the bowels. He then illustrates the case of the cow and the lion—the one living upon grass and having a semi-fluid motion every hour; the other gorging on flesh wherever he can get it, and not having a motion more than once a month. We might say, what a pity he did not eat straw like the ox. which in some happy future time he is to do; but then, like my other proposition, what becomes of the wise laws of the Creator which never alter, and in whom there is no change or shadow of turning? Truth is truth from the beginning to the end. It is this fact which enables men to whom he has given minds and intellects to find them out, and unless they always were the same man could never know anything at all; there never would be any fixed points; everything would elude him; whereas he knows what he does from the sheer stability of all Nature's and natural laws. The cow illustration is not a very happy one, for how is it with her husband, the bull, who lives along with her on the same grass, and he has few motions a day, and those rather solid. How is it with the sheep, and deer, and the goat, who all have scybalous motions, the very opposite of the cow. Take horses out at grass, if they are in health, their motions are consistent and not too frequent. How is it that in many persons who eschew much meat and live principally on vegetables, and those who have become entirely what are called vegetarians, that they are not free from constipation? Take those who consume, on the contrary, more meat in proportion to vegetables, they are often very loose fellows in their bowels, while those who mix both are sometimes costive, sometimes loose.

I take myself a fair proportion of both meat and vegetables, and being in good and robust health, am what may be justly called a very regular man; but if in the spring I eat largely of currants, strawberries, raspberries, cherries, and all these early fruits, I become costive; the more I eat the more costive I become. This autumn I have eaten largely of peaches, nectarines, plums, greengages, pears, &c.; the same fact occurs, and instead of taking physic I am obliged to take some good hard Sussex puddings, made of nothing but flour and water, and when cold would be no bad substitute for the ball cartridge of a small howitzer in the absence of one of iron. Take the peculiar diet of counties and different nations, and it will be found that neither constipation nor looseness depends on the food. Nor as man "departs from that of the lion to that of the cow," does the physiological phenomena of the state of the stools depend. If we are to prefer the *secundum naturam* to the *secundum artem*, let us go a little deeper into the matter than we have hitherto done, and we may find out something that will explain all these facts better. In the artificial state man is in, many theories have been made by empiricism on the treatment of his disorders. Let the individual feed on anything he pleases, even as a carnivora or a vegetarian, or on the mixed diet, constipation may occur, and this is not to be cured by aperients, but it may be by tonics. Constipation is often a state to be encouraged, for it is a conservative action. This Dr. Radcliffe has observed, especially in "old age and debility." Now, I have known old Medical men and physicians of reputation that have hugged their dogmas to the last, complaining that their bowels did not act so regularly as formerly, and fly to their dinner pills and confection of senna, and then wonder they lose brain power and become forgetful, and lose their memory. Dr. Radcliffe says, in these stages of life, that "it may be assumed that the digestive powers are feeble." Now, many old people in this state, though they have lost most of their teeth, can and do take an enormous amount of food, animal as well as vegetable, and their digestion is most vigorous for they seem always ready for their meals, and get querulous if delay occurs, showing that this constipation with them does not depend on their food. Then, to make those whose idiosyncrasy is constipation have a daily motion, "after the manner of many," "must have the effect of starving the system by removing the food from the bowel before digestion and absorption have had time to do their work." Now here is some confusion. If chyle is meant and this is removed too quickly from the small intestines and carried into the colon, and the fæces, consequently, too quickly and inordinately purged out of the large intestine, then there is a double loss, and I can understand the case; but the food is only mentioned which has nothing whatever to do with the action of the fæces in the colon. The physiology of these are so entirely different that I see plainly where all the errors arise in all these questions. However, Dr. Radcliffe has broached the subject in the old and usual style, and pursued the same beaten track, looking only to the food and its digestion without a thought of the uses of the fæces in the physiology of the colon itself, and their influence on the general system. The uses of the fæces being apparently not understood at all, and the colon, which is one of the most intelligent, if I may use the term, of the whole

viscera, as well as the only true conservative organ we have in the body, has not been understood. These are questions of such mighty import, and capable of being explained far differently from what they have, that in following up this subject I hope to throw some new light upon it.

I am, &c., CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

SOCIAL SCIENCE CONGRESS AT SHEFFIELD.

HEALTH DEPARTMENT.—PRESIDENT, DR. LANKESTER.

In this department, over which Dr. Lankester presided, Dr. J. C. Hall, the Senior Physician to the Sheffield Public Hospital, read a paper on the subject which has attracted much attention both in and out of the town in which his remarks were delivered—viz.:

"THE EFFECTS OF CERTAIN SHEFFIELD TRADES ON LIFE AND HEALTH."

The parish of Sheffield (said Dr. Hall) is of considerable extent. It is more than ten miles in length; its average breadth three miles, with an area of rather more than 22,000 acres. At the last Census the population was 185,157, being an increase in ten years of 49,874. The present population of Sheffield is more than 200,000. The number of houses at present, I am informed is 43,563, and of these 39,664 are inhabited and 3,900 uninhabited. The last return made to the town-clerk showed the rateable value of the property in the borough to be 498,641*l.* 7s. 4d. In the ten years ending 1860 the death-rate was 28 in 1,000; in 1863, 34 in 1,000; in 1864, 34 in 1,000; and for the first six months of the present year we find it at the rate of 32 in 1,000; and even admitting a slight error in this return of the Registrar-General, based as it is on our population, at the last Census, nevertheless, the death-rate of Sheffield must still strike with alarm every-one who gives the subject his consideration. Sheffield has very rapidly increased in size and importance; for in 1615 the population was only 2,207. In 1736 the township of Sheffield consisted of 2,152 houses, with a population of 9,695. Many of our local trades can be carried on with a very small amount of capital, and hence the very large number of what are called little masters. The wages of many of the artisans are also much higher than in other towns. Few towns have more pure and better water than Sheffield. The supply of all the necessaries of life is abundant, and generally reasonable in price. Most of the artisans have a house of their own, and those who live in the suburbs have frequently a garden. In times of good trade it is not usual to find two families under the same roof, and I do not think we have an inhabited cellar in the whole town. The average number of inmates to each house is rather more than five, and many of these dwellings either front the street or open into moderately-sized yards. The recent adoption of the Local Government Act by the Corporation of Sheffield will have a most beneficial effect, so far as the erection of houses for our artisans is concerned. There is probably less of the confined alley and narrow *cul-de-sac* in Sheffield than in many other manufacturing towns. A good deal has been done of late years to the sewers and surface drains of the town, but still much requires to be done to improve the sanitary condition of the inhabitants. The manufactures of Sheffield are—knives, scissors, razors, files, edgetools, joiners' tools, engineers' tools, scythes, sickles, shears, saws, circular saws, steel, railway springs and rails, buffers, anvils, vices, steam hammers, boilers, engines, stove grates, fenders, fire-irons, silver, silver-plated, Britannia metal goods, &c., to which must be added the more recently introduced manufacture of armour-plates, guns, and steel shot. The lead works of Sheffield were established in 1758, and now employ about forty men and twenty women. Although as old as any works in England, no better precautions are taken to preserve the health of the workmen than at any of the more modern establishments. Men are now working who have been employed at the Sheffield Lead Mills 6, 8, 12, 13, 14, and in two cases 30 years. The forging, grinding, cutting, and hardening of files form one of the most important branches of our local trades, and one in which the workmen suffer most severely—at any rate, in one part of the manufacture of a file. This is one of the trades which is "in union," and consequently one the numbers employed in which can readily be ascertained. At present there are engaged in the file trade:—Forgers and cutters, 3,500; file-grinders, 250; hardeners, 200; females, 300; boys, 1,000; dressers, strippers, and coke riddlers, 300; managers, 200—total, 5,750. If to this number we add the manufacturers, and those not connected with the union, it will be seen that more than 6,000 of the inhabitants of Sheffield and its vicinity are engaged in the manufacture of files. The Filesmiths' Union is one of the most powerful in Sheffield. From 1854 to 1865 it has paid to its members when out of work, 51,044*l.* 17s. 2½d. From 1860 to the end of 1864 (five years), this union paid for 312 deaths—297 men and women, and 15 boys, 1,156*l.* 16s. The wages of the better class of double-handed forgers will average about 40s. a week; single-handed forgers, 25s. to 30s. a week; cutters of a superior class of work, 30s.; boys, 6s. to 18s.; female cutters, 6s. to 18s.; scourers, &c., 9s. to 12s. a week. Now, what is the file-cutter's disease? Poisoning by lead. The file rests on a bed of lead during the process of cutting, and that fine lead dust may be seen to rise every time the chisel is struck by the hammer. The men have a foolish habit of wetting the finger and thumb with which the chisel is held by licking them. They frequently eat their meals without washing their hands, and often take dinner in the workshop where the files are cut—as though fine lead dust, handling the lead at each shifting, and licking the fingers were not sufficiently efficient poisoners. I saw in one of the file-cutters' shops, during the last few weeks, a man whose wife had just brought him his dinner eating it with unwashed hands, and dipping his fingers, blackened and covered with fine lead dust, into a paper which contained the salt for seasoning his beef. I went in (Sept. 25) to a file shop in which several men were at work cutting. These men all took their dinners in the shop—they never wash their hands until they get home at night—"sometimes not then." They do not change their clothes when they get home. One man made this statement:—"I have known a thousand file-cutters, but I only know one who takes the trouble to wash his hands before he gets his dinner; he works at Cammels. I never think of washing mine." With regard to the symptoms of lead-poisoning, I need not dwell on them at any length here. The file-cutters, after repeated attacks, have a peculiar dirty white and sallow appearance; the dropped wrist is common, and the blue line round the teeth, arising from the deposition of sulphuret of lead, very marked. A boy was admitted into the Sheffield Public Hospital a few weeks ago. He had all the symptoms of lead-poisoning, except the blue line; being a file-cutter, no doubt existed as to the nature of the disease. Iodide of potassium was given to him, and in a week the blue line appeared. If formed, it is difficult to say when it will disappear. I once had a file-cutter under my care who had suffered in early life from lead colic; he had not however cut files for eighteen years before I saw him, nor had he been in any way exposed to the influence of lead. The blue line was still present. With respect to hardening files in lead producing the file-cutter's disease, the men who work at it say, "that they sometimes feel ill," and they consider it injurious to health. My own experience leads me to say that it most certainly is not nearly so injurious as file-cutting. At the Sheffield Public Hospital and Dispensary, where we have had the last two years 56,858 in and out-patients, and to which the Filesmiths' Union annually subscribe 52*l.* 10s., to have the privilege of sending the poor brethren of the trade when sick, I do not remember to have seen the last ten years a file hardener suffering from lead colic. I saw one with the blue line,

but he had only hardened in lead for a short time, and had been a cutter previously for many years, and had often been a sufferer from the file-cutter's disease. Dr. Hall suggested attention to the following simple rules for the prevention of the file-cutter's disease :—

"*a.* Children ought not to begin to cut files at so early an age as at present; it tends to make them feeble in body, and deprives them of the possibility of being properly educated.

"*b.* Without the greatest care, lead will enter the system through the skin. Common sense will therefore point out the importance of washing the hands, arms, and face many times a day—of frequently combing and brushing the hair, and of having one set of clothes for the shop, and another when out of it. The mouth ought also to be frequently rinsed with water.

"*c.* The meals ought not to be taken in the workshop, and never taken without first washing the hands, arms, face, and lips, and changing the working jacket, or the poison will enter the system with the food.

"*d.* On no account lick the fingers when at work.

"*e.* An orinasal respirator worn when working would keep out much of the fine lead dust, and consequently keep the poison from entering the air passages.

"*f.* The dress should be of coarse linen—a cap of the same material would keep the lead dust from the hair.

"*g.* The working dress and shirt should be put on when entering the shop, and both should be changed for the ordinary dress before going home.

"*h.* On no account neglect the use of the hot and cold bath.

"*i.* Attached to every large manufactory where files are cut, there ought to be a large room supplied with hot and cold water, where the men could wash themselves and change their dress."

The Sheffield grinders' disease was formerly almost unknown, and for this reason, until the year 1786, when the first steam wheel was erected, grinding wheels were built upon the banks of rivers in and near Sheffield; and water being the power employed, it will be obvious that the grinder would have many interruptions to his trade, and that to grind day after day as the grinders now do was then impossible, and many of them were makers as well as grinders of cutlery. Nor was this all. By the old regulations of the Cutlers' Company, passed in the reign of Elizabeth, it was provided, "that no person engaged in the said manufacture, either as a master, servant or apprentice shall perform any work appertaining to the said science or mystery of cutlers for eight-and-twenty days next ensuing the 8th day of August in each year, nor from Christmas to the 23rd day of January, upon pain and forfeiture, for every offence found and presented by twelve men of the said fellowship of the sum of twenty shillings. No person occupying any wheel for the grinding of knives to allow of any work being done during the holyday months; penalty as before. When grinding became a separate branch of trade, their hours were no longer limited, and then, it would appear, that the fearful effects on the animal economy of constantly inhaling particles of steal and grit day after day began to develop themselves. This, then, leads me to a first practical suggestion for alleviating the condition of the grinders—viz., to diminish the hours of labour; and the most effectual way to do this is to abolish "saint days," as the first days of the week are called by these men, and which are spent by but too many of them in drunkenness and intemperance. What is the result? They crowd into three or four days the labour that ought to be distributed over the whole week, and many soon find, to their cost, the folly of such proceeding. It is a notion in some of the hulls that a drunken grinder often lives the longest. This is a very great mistake. Intemperance has hurried hundreds of these men into their graves. I almost invariably find that so soon as the liver becomes affected the chest symptoms are aggravated, and that when the liver fails to discharge its functions a comparatively slight amount of disease in the lungs of the grinder will cause far more distress and difficulty in breathing than even in lungs more extensively diseased, when this organ acts properly. By limiting the hours of labour time would be afforded for out-of-door pursuits, in exercises which would bring the different muscles of the body into play, and prevent, especially in the young, some of the effects which result from bending over the wheel when at work. I have had to day in my study a razor grinder, at the Union Wheel; he is now 46, strong and healthy, he has never suffered from the grinders' disease, he began to work at 11, and he justly expressed the opinion that "grinding takes most hold of young boys." He has always used a fan, and will not work in a hull with dry grinders who are not so protected. He does not believe in "saint days," and works on an average about 38 hours a week. It would be well, therefore, 1, to limit the hours of labour both in boys and men; 2, wet and dry grinders ought on no pretence to be allowed to work in the same hull; 3, to oblige the owners of all wheels to provide a fan for every dry grinder, and to see that this fan is always kept in proper working order. I propose that the owner of the wheel, and not the grinder, should provide the fan and see that it works properly. If the grinders are left to provide it for themselves, so reckless of life, so careless and indifferent are many of the fork, scissor, and razor grinders, that I am certain they will never provide it for themselves. Let me give some evidence in proof of this. In one hull I found a man shaping razors with a first-class fan. There was much dust—the fan was not working; he had not taken the trouble to affix the band, and that necessary act would have taken perhaps half a minute. In another hull a scissor grinder had a good fan, and spoke to me of its "wonderful advantages"—"if they cost a hundred times as much as they do, they are worth it; no dry grinder can live without them"—and yet this man permitted a razor grinder to work without a fan on his right hand and on his left, and to cover him with their dust. In another hull, in which five dry grinders were at work, the fans had not been used for three weeks—the wheel band was wrong; and yet these men went on destroying themselves rather than do to the wheel band a quarter of an hour's work—all that was requisite to set the fan in motion. A most intelligent scissor grinder, who has now left the trade, at which he began to work when only nine, told me he "always used a fan." He once offered to five scissor grinders who worked in the same hull with him to put a fan at his own cost, and to take the price of it from each by instalments of 1s. a week. They one and all refused his kind offer. I find hull after hull in which scissor, razor, and fork grinders are now working without fans; some are working in a very confined space without them, two and three deep. One man, a scissor grinder, told me "it was not worth while to get one for the bit of time he had to live." I only found one fan in all the hulls I visited attached to the polishing machinery. I think that where polishing is carried on a fan ought always to be in use. I visited one hull in which an intelligent man at one end had put up a fan for each "trow," and for which he charged each fellow workman a penny a week. The man working next to him had paid his penny for the fan, but having been too idle to fix a box, it was useless. Others I found with a fan fixed, but not at work, because "they did not like the noise," and I have many times been told by dry grinders "the trade was full enough as it was, and that if the men lived longer it would be so full there would be no getting a living at it." What can you say to such men—to dry grinders working without a fan? Why this—if ever there was a trade more poisonous than the fabled valley of the upas—more slow in its effects it is true, but equally deadly with the inhaling of the atmosphere of the celebrated Grotto del Cani, it is that of a fork, a razor, or a scissors' grinder, who works without employing the effectual means for his preservation which the fan affords. If bent on destroying yourselves thus recklessly, have the honesty to prevent others, the poor little boys, many of them your own sons, from entering the trade without a warning. Write, therefore, over the doorway leading to your infernal hulls,

"All hope abandon ye who enter here."

The entrance to a dry grinder's hull, without a fan, I say

emphatically, is unmistakably the gate that leads to certain death. To prevent the grinder's disease I am of opinion, fourthly, that all wheels should be placed under proper inspection, properly ventilated and kept clean, the rooms built of a proper height, with sufficient space for each man, and every wheel properly provided with conveniences, the want of which or the substitutes for which at many wheels are a disgrace to the civilization of the nineteenth century, and in a sanitary point of view a great evil. No floor should be of mud. Where wet grinding is carried on, the floor should be flagged with a sufficient incline to let the water run off. Lastly, children should be prevented from entering the wheels at an early age. Sir, may I read what I wrote in 1857? "To send a boy at eight or nine years of age into a grinding hull is an act of refined cruelty which the powerful arm of the law can alone restrain. The application of the Factory Act to the grinding trades of Sheffield, would, in my opinion, be most wise and salutary. These helpless children I would, indeed, commend to the protection of the State; and glad, indeed, shall I be if these remarks attract the eye of any member of the House of Commons, and induce him to bring the question before Parliament; or if the evils, religious, moral, and physical, under which these poor boys are suffering, lead the inhabitants of Sheffield to petition the Legislature to cast around them that protection which they have not at present." Such was the opinion I published in my work on "The Causes, Prevention, and Treatment of the Sheffield Grinders' Disease" eight years ago. I repeat that opinion now, and right glad am I to see it in every respect confirmed by the evidence collected by Mr. White, and by the recommendation made to Her Majesty by the Children's Employment Commission.

Dr. Lankester, the President of the Department, opened the business by giving an extempore address on the best means of preventing the spread of contagious diseases. He defined contagious diseases to be those which were capable of being communicated by one person to another by specific poisons generated in the system. He considered small-pox as the type of all such diseases, and that reason and analogy showed typhus fever, typhoid fever, scarlet fever, measles, whooping-cough, and cholera belonged to the same group of diseases. Practically, it was of the utmost value to recognise the contagiousness of these diseases. In dealing with them, three great facts must be regarded, viz. —1, the poison-maker; 2, the poison-bearer; 3, the poison taker. He looked upon the poison of these diseases as produced in the blood, and pointed out as the best means of destroying it, with dilution, oxidising, iodizing, chlorinizing, and the like. The poison-bearers were air, water, and dead organic matter. Those who dwelt amid dirt and filth were most disposed to contagion, but he did not believe that any amount of filth would generate a contagious disease.

Lord Brougham said that by acting as if such diseases were contagious they could at least do no harm, whereas if they thought they were not contagious and accordingly took no precautions, they made a fearful mistake in the event of any disease happening to be contagious.

In the discussion which followed a variety of opinions were expressed as to the means by which diseases were spread, and also as to the contagion of scarlet fever, typhoid fever, &c.

Mr. Goodwin said the best means for preventing the spread of contagious diseases were—pure air, plenty of pure water, and plenty of good food. He believed in these much more than in all the obnoxious quarantine regulations that could be devised. When he arrived in Sheffield he had hardly entered his bedroom when the dreadful smell from the river Don caused him two hours' illness. This river was a disgrace to Sheffield, and, if the cholera broke out, woulk cause the town to be decimated.

Alderman Saunders defended Sheffield from some of the attacks which had been made upon the authorities of the place for neglecting proper sanitary measures.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on Sep. 30th, the following Members of the College were duly admitted Fellows of the same:—Francis Edmund Anstie, M.D., Lond., Wimpole-street; William Roberts, M.D., Lond., Manchester.

At the same meeting, the following gentlemen, having undergone the necessary examination, were admitted Members of the College:—Robert Charles Brown, M.B., Lond., Preston, Lancashire; Pierre Georges Cox, Mauritius; David Owen Edwards, Florence; Balthazar Walter Foster, M.D., Erlangen, Birmingham.

The following were reported to have passed the Preliminary Examination in the subjects of General Education:—James Prime Bartlett, Notting hill; John Richard Barnegartner, Gorleston; John Bolton, Gower street; William Cheetwood, Waltham Abbey; Andrew Clark, Kensington gardens square; Thomas Collens, Birmingham; Frederick William Elliott, Turnham green; William Hodges Bristow, Ethelbert Hosking, Woburn square; Henry Enswor Jackson, Highbury grove; Frederic Loscombe, Bath; Charles Henry Mayhew, Upper Berkeley street; Charles Mills, Guilford street; James Part, Camden road; George Henry Pedler, Fleet street; Richard Porter, Droitwich; Arthur Milson Roberts, South Norwood; William Egerton Saunders, Peckham; Arthur Charles Simon, Upper Westbourne terrace; David Smart, Cranbrook; Charles Fox Webb, Basingstoke.

APOTHECARIES' HALL.—The following gentlemen and lady passed their examination in the Science and Practice of Medicine and received certificates to practise on Sept. 28th:—Colles Litchfield Anderson, Berkeley gardens, W.; William Henry Dixon, John street, Sunderland; Elizabeth Garrett, Upper Berkeley street, Portman square.

The following gentlemen also on the same day passed their first examination:—John Coyle Bailey, Middlesex Hospital; James Frederic Badle, Middlesex Hospital; John Rees James, Middlesex Hospital; Robert Pollak

THE CHOLERA IN PARIS.—The 'Temps' having published a letter from Dr. Vacher announcing some cases of cholera in the hospitals of Paris, and complaining that the head engineer of the Paris waterworks had refused to permit him to take samples from the reservoirs to examine them with the microscope, has received an official *communiqué* on the subject. The *communiqué* states that the administration of the city of Paris do not consider themselves bound to submit the contents of their reservoirs to the first person who asks for them. The analysis of water is an extremely delicate operation, which has never been refused to those whose names are known to the scientific world, such as Boutron-Charlard, Robinet, Hervé, Mangon, Grimaud de Caux, Poggiali, and others, who have composed notable treatises on the Paris water, but which it is prudent to refuse to a person who avows that he entertains feelings hostile to the municipal body. The authorities, in consequence of the insinuations of Dr. Vacher, tending to attribute to the waters of Paris some cases of cholera, do not forget that at the first appearance of the epidemic in 1832 a report was spread among the population that the water had been poisoned, and that this absurd rumour was the cause or pretext for the most lamentable incidents. Explanations which follow, moreover, will show that the Municipal Council, which cannot control atmospherical derangements, have done all that was possible to protect Paris from the drought which prevails throughout the Empire.

NEW ST. THOMAS'S HOSPITAL.—The preparations for the erection of the new St. Thomas's Hospital, in accordance with the plans for the Thames Southern Embankment, on the site selected at Stangate, are actively progressing, and the last arch of Westminster-bridge is now stopped by fences of piles, to prevent boats &c. interfering with the work of pile-driving for the dam, in which will be laid the foundation stone of the hospital.

POOR-LAW BOARD INQUIRY AT THE EAST LONDON UNION.—CHARGE AGAINST A MEDICAL OFFICER.—Mr. Farnall, the Poor-law Board Commissioner, has been holding an inquiry relative to the management of the East

ndon Union, at Homerton. The proceedings occupied
days, and no small portion of the time was taken up in
uiring into a fertile source of Poor-law discord—the
thod of keeping the infirmary books. From the evi-
ice taken by the Commissioner, it was shown that Dr.
irke, who had been the Medical Officer of the Union for
lve years, was, through a severe accident, prevented
m personally attending to his duties, which were under-
en by his partner, Mr. Niblett, and this gentleman on
day visiting the infirmary as usual was refused admis-
n by, it appeared, the order of the master. The master,
has been in office for a few months, was called, and
stated that he had received the guardians' authority for
using admission to Mr. Niblett, and they had given him
authority on his complaining of the incivility of Mr.
blett to his wife (who is matron) and himself. This
ivility, he went on to say, was "not so much in words
n manners," as Mr. Niblett showed a marked want of
rtesy towards them. This witness then brought forward
st of what may be called "imperfections in the work-
se Medical relief book," such as persons who were dead
ng kept on the book as still in the infirmary, and others
ng registered as still under Medical care who had been
ed into the body of the house. These were simply
rsights, and the rations of these dead and absent persons
never been drawn by the master, as the fact of the
nges had been otherwise known to him. That the
lical relief book should be kept perfect could hardly be
ected, seeing that the keeper of the imbecile patients
the copying out of the diseases and dietary, an imbe-
copying the names, and a sick pauper in the infirmary
ring the attendances. It was allowed by several of the
nesses that Dr. Clarke and Mr. Niblett were both
ane and attentive to the sick patients, and, in fact,
e was no complaint on this score, and no expression of
vility on the part of Mr. Niblett was shown; while, on
other hand, it was said that the master and matron
rude in their manners and overbearing. Dr. Clarke
the guardians desired him to name another substitute
e place of Mr. Niblett, but this he refused to do. Mr.
all refrained from expressing any opinion on the
ts of the case, but said the whole matter should be
before the Poor-law Board, from whom the guardians
d hear.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, OCT. 11.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, OCT. 12.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, OCT. 13.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, OCT. 14.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

MONDAY, OCT. 16.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metropolitan Free Hospital, 2 p.m.

TUESDAY, OCT. 17.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

MR. G. CROXTON.—The appointment is inserted.

DR. PURDON'S paper is unavoidably postponed until next week.

MR. NEIL MCGREEVY.—The letter is received, and will appear next week.

MESSRS. CASSELL.—The card has been received.

DR. J. N.—The newspaper has been received.

Mr. J. H. R.—The subject shall receive early attention.

PRIZE OF THE BRITISH MEDICAL ASSOCIATION.

e Subject selected by the Committee of Council for competition in 1866

is "ON SHOCK AFTER SURGICAL OPERATIONS AND INJURIES."

he Prize consists of a Gold Medal, value Twenty Guineas, called the HASTINGS MEDAL.

he Essay must not be in the Handwriting of the Author, nor exceed in length twenty-four pages of the BRITISH AL JOURNAL.

must be forwarded to the General Secretary on or before the 1st of July, 1866, under cover, together with a sealed pe bearing the motto of the Essay, and containing the Author's Name and Address.

ie successful Essay is to be considered the property of the Association, and will be published in the JOURNAL.

T. WATKIN WILLIAMS, General Secretary.

ewhall street, Birmingham, September 28th, 1865.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 7S FARRINGDON STREET, CITY.

Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other makers. ——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments, for 6 stamps.

ESTABLISHED 1848.

Mr. J. Baxter Langley, M.R.C.S.

Eng. (late of King's College, London), PROFESSIONAL AGENCY, 60 Lincoln's-inn fields, W.C.

Country Practices.—Mr. Langley

begs to call the attention of young professional men seeking openings for practice to his Register, which, at present, contains a large number of very eligible openings, death vacancies, &c., in the country (with and without public appointments), requiring the investment of only a moderate amount of capital, yet offering a good prospect of fair and prompt returns. Applicants may rely that nothing will be recommended as an investment which Mr. Langley does not believe to be bonâ fide and suited to the circumstances of his clients.

Medical Investments.—Gentlemen

wishing to commence practice, and having capital at their disposal (from 100*l.* to 4,000*l.*), are informed that Mr. Langley has now upon his list upwards of 150 bonâ fide partnerships and practices for negotiations. Professional Agency. Office hours 11 till 4.

Liquor Folii Ricini, or Fluid Extract

of the Palma Christi Plant, for increasing the Secretion of Milk in Suckling Women.

Mr. GREENISH solicits the attention of the Profession to the above preparation, which is now in great demand.

Dose: One teaspoonful three times a day.

Prepared by THOMAS GREENISH, Chemist, 20 New st., Dorset sq.

Superphosphate of Iron and

SUPERPHOSPHATE of IRON and LIME.—Particulars of these new and valuable remedial agents will be forwarded on application, by Mr. Greenish, 20 New street, Dorset square.

Jozeau's Copahine Mege.—Copaiba

and Cubebs are doubtless the best remedies, but are of a repulsive taste and odour, and occasion colicky pains, nausea, and gastric disturbance. M. Jozeau has succeeded in rendering them perfectly innocuous by increasing all their curative properties. It has been adopted by the Paris Academy of Medicine after more than a thousand trials in Paris and the different London hospitals, viz., St. Thomas's, Guy's, and St. Bartholomew's, under the care of Messrs. Lloyd, Poland, and Legros Clark. —'Lancet, Nov. 6, 1857. The Copahine, which is in form of a pretty pink sugar plum, effects a cure in about six days. 100 Capsules, 4s. 6d.; post-free, 5s. 2d.—At G. JOZEAU'S, French Chemist, 49 Haymarket, London; 22 Rue St. Quentin Paris; and all Chemists.

Medical Fixture & Glass Warehouse.

—W. HAY and SONS, 24 and 25 Little Queen street, Lincoln's inn fields, beg to inform the Profession that they Fit-up every description of Medical Shops and Surgeries, and have in Stock a large assortment of New and Second-hand Drawers, Counters, Desks, Dispensing Screens, Bottles, Jars, and every requisite for the above.—A large Assortment of Medical Lamps

James's Fever Powder, 4s. 6d. per

bottle; packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all wholesale Druggists.

Flour — (Essex) — Warranted free

from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs.) 9s. 0d. Households (recommended for bread-making), 8s. 4d.; Seconds, 7s. 8d.; Wheat Meal for brown bread, 7s. 8d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any railway station 200 miles. German yeast.

CHOCOLAT-MENIER.

The healthiest and most delicious Aliment for Breakfast known since 1825

ANNUAL CONSUMPTION EXCEEDS 4,000,000 lb.
Defies all honest competition.
Unadulterated, PURE, and highly nutritious.

Wholesale—23 Henrietta street, Covent-garden. Retail—BATTY & CO. 15 and 16 Finsbury pavement, E.C.: and all respectable houses.

TO THE MEDICAL PROFESSION.

Bragg's Charcoal Biscuits for

INDIGESTION, HEARTBURN, &c. &c., manufactured from the purest Vegetable Carbon. Sold only in tins, at 1s., 2s., 4s., and 8s. each, by J. L. BRAGG, Sole Manufacturer, 2 Wigmore street, Cavendish square, London. Also "IRON TONIC BISCUITS," in 2s., 4s., and 8s. Tins.

Chemists and others allowed a liberal discount.

Post-office Orders made payable at the Old Cavendish-street Branch.

Medical Transfer and Partnership.

30 BUCKLERSBURY, LONDON.

Mr. Orridge, Medical Transfer

Agent, Referee, and Valuer of Medical Property may be consulted, as usual, at the above address

Office Hours, 11 to 4.

BASS'S EAST INDIA PALE ALE

BARCLAY'S PORTER AND STOUT,

In 18-Gallon Casks, Bottles, Half-Bottles, and Imperial Pints.

ALSO

DEVONSHIRE CHAMPAGNE CIDER.

BERRY BROS. & CO.,

3 ST. JAMES'S STREET, LONDON, S.W.

S. V. R, 56° Over Proof

First Quality, 20s. 6d. per Gallon.

This quotation admits of neither credit nor discount, and is for quantities of not less than two gallons.

HENRY BRETT & CO., DISTILLERS,
HOLBORN and REGENT STREET.

Hedges & Butler, Wine Merchants

&c., recommend and GUARANTEE the following WINES:

SHERRY.

Good Dinner Wine, 24s., 30s., 36s. per dozen; fine pale golden and brown sherry 42s., 48s. 54s., 60s.; Amontillado, for invalids, 60s

CHAMPAGNE.

Sparkling, 36s., 42s.; splendid Epernay, 48s., 60s.; pale and brown Sillery 60s 78s. Veuve Clicquot's, Perrier and Jouet's, Moet and Chandon's, at

PORT.

For ordinary use, 24s., 30s., 36s., 42s.; fine old "Beeswing," 48s., 60s. choice Port of the famed vintages, 1847, 1840, 1834, 1820, at 72s. to 120s.

CLARET.

Good Bordeaux, 18s., 20s.; St. Julien, 24s., 30s., 36s.; La Rose, 48s. Leoville, 48s.; Latour, 54s.; Margaux, 60s., 72s.; Lafitte, 72s., 84s., 96s.

WHITE BORDEAUX.

Good Dinner Wine, 24s., 30s.; Barsac, 42s., 54s; Sauterne, 42s., 48s. 60s., 84s.

BURGUNDY.

Macon and Beaune, 30s., 36s., 42s.; St. George, 42s.; Chambertin, 60s. 72s.; Côte Rôtie, 60s., 72s., 84s.; Corton, Nuits, Romanée, Chambertin, Vougeôt, &c.; Chablis, 24s., 30s., 36s., 42s., 48s.; Montrachet and St. Peray, sparkling Burgundy, &c.; Chablis, 24s. 30s., 36s., 42s.

HOCK.

Light Dinner Hock, 24s., 30s.; Nierstein, 36s., 42s.; Hochheimer, 48s. 60s. 72s.; Liebfraumilch, 60s., 72s.; Johannesberger and Steinberger, 72s. 84s., to 120s; Assmanshausen, a choice Red Hock, 48s., 60s.

MOSELLE.

Still Moselle, 24s., 30s.; Zeltinger, 36s., 42s.; Branneberger, 48s. Muscatel, 60s., 72s.; Scharberg, 72s., 84s.; sparkling Moselle, 48s., 60s. 66s., 78s.

Foreign Liqueurs of every description. On receipt of a post-office or reference, any quantity will be forwarded immediately by

HEDGES & BUTLER,

London: 155 Regent street, W.; and 30 King's road, Brighton.

ORIGINALLY ESTABLISHED 1667.

Kinahan's LL Whisky v. Cognac

BRANDY.

This celebrated Old IRISH WHISKY rivals the finest French brandy. It is pure, mild, mellow, delicious, and very wholesome. Sold in bottles, 3s. 8d. each, at most of the respectable retail houses in London; by appointed agents in the principal towns in England; or, wholesale, 8 Great Windmill street, Haymarket.—Observe the Red seal, pearl stopper and cork branded "Kinahan's LL Whisky."

Dotesio's Dépôt, 95 Regent street, Quadrant

For the Sale exclusively of the fine Bordeaux, Burgundy, Champagnes, and Cognacs of France, in their pure natural state

Cellars and Counting-house as above, and Orders taken also at the Restaurant,

No. 9 RUE DE CASTIGLIONE, PARIS.

LADIES' SURGICAL BELTS,

Abdominal Supporters, Elastic Stockings and Bandages, Fracture Trusses, Chest Expanders, Spinal Corsets, Instruments for Piles, Prolapsus Ani and Uteri, and every description of Mechanical Appliances, with all the latest improvements, manufactured at reduced prices by

Mr. CHANDLER, 66, BERNERS ST., OXFORD ST.

A lady of great experience attends. Illustrated Catalogues forwarded. A liberal discount to the Profession.

Aloina.—T. and H. Smith,

Discoverers of this,

THE CRYSTALLINE PURGATIVE PRINCIPLE OF ALOES (vide 'Edinburgh Monthly Journal of Medical Science' for Feb. 1856), continue to prepare and supply it. They have the gratification of knowing that the most eminent of the Profession prescribe it, to the exclusion of the gether of the various kinds of aloes.

Orders executed direct, or through any Drug House, by T. & H. SMITH and CO., 69 Coleman street, City, London, and 21 Duke street, Edinburgh.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ASES OF CUTANEOUS DISEASE.

By Henry Samuel Purdon, M.D.,
L.R.C.P. Edin., L.R.C.S.I.

'sician to the Belfast Dispensary for Diseases of the Skin; ıssistant Physician Belfast Charitable Infirmary; late Clinical ıssistant Glasgow Dispensary for Skin Diseases.

Eczema Rimosum.

. S., æt. twenty-six, admitted at the Belfast Dispensary Skin Diseases on September 9th, suffering from an ematous eruption of the ring-finger of the left hand, senting all the appearance of the disease described by M'Call Anderson as eczema rimosum.

listory.—The disease has existed for about three years; nerly the patient had been obliged to wash a good deal. ore coming to the dispensary various plans of treatment been tried.

'resent condition.—The finger is somewhat enlarged, this doubt arising from subcutaneous infiltration. Fissures end in various directions. Complains of considerable ıiness in the affected part.

'reatment.—Painted the finger with a solution of potassa ı (ten grains to the ounce of water). This did not ısion much pain. In a week she returned to the dis-sary. I now painted the diseased surface with a ıtion containing thirty grains to the ounce, which caused ıruption of vesicles in a few minutes. Its action was ped by means of cold water. Calomel ointment to be future dressing.

eptember 30th.—Discharged cured. The above plan of tment I have seen frequently used at the Glasgow Dis-sary under Dr. Anderson and the late Dr. Buchanan. potash solution seems to fulfil a two-fold object—viz., *ting* a healthy action in the part, and dissolving the ened cuticle.

Eczema Impetiginodes of Head.

Brown, æt. eleven years, an inmate of the Belfast itable Institution, was admitted into the infirmary ing from a pustular eruption of the scalp on 29th.

story.—He informed me that the disease had existed out one month.

sent condition.—The hairs are glued together from the arge, which is rather offensive. Appetite good; ls regular, and the patient presents no signs of a ious diathesis.

eatment.—The hair to be cut short, after which a ice is to be applied. The affected part to be dressed citrine ointment, and to have three drops of Fowler's ion three times each day.

y 24th.—No signs of improvement taking place, I have ll the hairs extracted from the diseased surface, after nanner recommended by Bazin, by means of the ing forceps. The disease having put on a chronic rance, I blistered the affected part with acetum can-lis, made with glacial acetic acid; after which a ice is to be applied. Future dressing to be the oxide ıc ointment.

gust 21st.—No appearance of any pustules; hair grow-ıpidly; all treatment to be discontinued.

Elephantiasis.

)., æt. forty-nine, admitted into Belfast Dispensary for Diseases on September 19th.

tory.—Was formerly a painter. The disease has l for about twenty-eight years. It commenced, ac-g to patient, from an eczematous eruption.

sent condition.—The left leg is greatly enlarged, and is extensively ulcerated at the calf. No hope of a cure can be entertained. On the right leg a slight eczematous eruption exists, which the patient states is similar in appearance to the eruption which occasioned the present disease.

Treatment.—Ordered the ulcerated surface to be dressed with linimentum calcis. Fowler's solution and cod-liver oil as internal remedies.

September 27th.—Ordered a lotion of sulphate of copper (five grains to the ounce of water) to be used as a dressing for the ulcer.

October 4th.—The sore has put on a more healthy appearance. To continue treatment.

Dracunculus.

Mr. Y. had been for several years on the west coast of Africa. After returning to this country, he complained of a pain and swelling on the right thigh. The swelling was opened by Dr. T. H. Purdon, of this town, and was found to contain four guinea-worms, which I have preserved. Mr. Y. considered the disease to have arisen from the bite of a small insect called *chigre*.

Alopecia Areata.

Mr. G. consulted me on June 12th, for a small patch of baldness, situated on the posterior part of the scalp.

History.—He attributed the disease to being in contact with a child similarly affected. This gentleman being tutor to the family, I had the opportunity of examining this boy, who was affected with alopecia areata (Porrigo decalvaris of Bateman).

The history of the manner in which the disease commenced is rather curious. It appears that the family to which the boy already referred to belonged, went to the sea-coast during the summer; whilst there, two of his younger brothers besides himself became affected, from playing with some poor people's children residing there. The above, I think, fully illustrates the contagious nature of this disease.

Present condition.—The bald patch is about the size of half-a-crown; in shape, circular. Skin white and shining. A few downy hairs are to be seen on it.

Treatment.—Extracted the hairs around the margin, after which blistered the affected surface with acetum cantharidis. Citrine ointment to be rubbed in night and morning.

July 29th.—The hairs are growing. No appearance of the parasites "microsporon andoninii" on any of the surrounding hairs.

REVIEW OF BOOKS.

Lectures on Venereal Diseases. By James A. Hammond, M.D. Pp. 287. London: Trübner and Co. Philadelphia: Lippincott and Co., 1865.

Some of these lectures were delivered by Dr. Hammond in the Baltimore Infirmary, in 1861, when he was one of the surgeons of that Institution, and they were published in the 'American Medical Times.' The rest of the lectures were prepared, but not delivered, owing to the author's departure from Baltimore to join the army, but they are written out from the original notes and the whole are brought up to the knowledge of the present day.

The lectures constitute in their present form, a valuable contribution to our knowledge of syphilitic diseases, and although many of the views entertained by Dr. Hammond will perhaps be questioned, it cannot be doubted that they are founded on practical knowledge and are argued with great force and clearness. The experience on which the lectures are based was chiefly obtained from military sources, and it is well known that for obvious reasons, syphilitic diseases can be better studied, throughout their history, among soldiers than among any other class of the community. The men report themselves as soon as the disease commences, they are generally able to trace the source of contagion, they are subjected to strict supervision during their treatment, and the after consequences are carefully watched. When therefore, Dr. Hammond's doc-

trines are in opposition to those usually maintained, it must at least be admitted that he gives reasons for his disagreement with existing authorities.

In the first place we may observe that Dr. Hammond is a firm supporter of the doctrine of the duality of the venereal poison, and he maintains that one kind of poison gives rise to a simple, non-infecting, soft chancre, and the other causes an indurated one liable to be followed by constitutional syphilis. He agrees with those who think that the two kinds of poison are not convertible into one another, but are essentially distinct, each inoculating with its own specific poison, and causing a sore of the same character as the parent chancre. He also maintains that there are two kinds of virulent gonorrhœa, one caused by the deposit of the matter of a soft chancre on a secreting mucous surface, and another due to the contact of the pus of an indurated chancre with such a surface. In holding this view that gonorrhœa is primarily due to the deposit of chancrous virus upon a mucous surface, Dr. Hammond is, it will be perceived, at variance with most writers upon the subject, but he brings forward many arguments and facts of a very weighty character in support of his views.

The question of the duality of the venereal virus is not, according to Dr. Hammond, a mere bare pathological problem, but is one of very great practical interest, and a mistake in diagnosis would lead to very serious and deplorable results to the patient, because the treatment advisable for the one would be wholly unsuited to the other. Mercury, in particular, which Dr. Hammond thinks exceedingly useful, though not indispensable, in the indurated form, is entirely contra-indicated in the soft chancre, and indeed, he believes that "in many cases, what is called constitutional syphilis is nothing more than the horrible condition produced by mercury administered in the treatment of soft chancres, which would not under any circumstances have been followed by syphilis. Ulcerations, pains in the bones, necrosis, cutaneous eruptions, and a failing of the powers of life, make up a combination which is too often regarded as a sequence of the venereal ulcer, but which is due in many cases to a failure to distinguish between the soft and indurated chancres, and to subsequent maltreatment."—P. 47. The local treatment recommended by Dr. Hammond in the soft chancre is the paste composed of sulphuric acid and charcoal as employed by Ricord, and very little constitutional treatment is required, as according to the views expressed in these lectures, no constitutional effects follow this form of disease.

The indurated chancre is of a very different character, and is the chancre *par excellence*. "It is the indurated chancre, because it alone possesses a true indurated base; it is the infecting chancre, because it alone poisons the system; it is the syphilitic chancre, because it alone causes syphilis; and it is the chancre, *par excellence*, because it alone possesses all those characteristics which I have mentioned—characteristics which have caused it to be studied by the most eminent men in the Profession, which have rendered it a terror to mankind, and which have therefore placed it high in the pathological scale above its more humble congener."—P. 62.

On the much vexed question of the administration of mercury in syphilis, Dr. Hammond entertains very definite opinions. Putting aside altogether the soft chancre, in which mercury is not only useless but injurious, Dr. Hammond believes that this metal is the most efficacious remedy for the indurated form of disease, and for the whole train of the so-called secondary, and even of some of the tertiary, affections. He does not deny, however, that syphilis may be cured, or in other words, that patients may recover, without the use of mercury, but he positively denies that it can be cured as speedily and as effectually without mercury as with it, and he considers it as much a duty to treat the disease with this drug as it is a duty to treat intermittent fever with quinine, although the latter disease may be cured by other drugs, or may even disappear without any treatment at all. Dr. Hammond, at the commencement of his military Medical career, treated syphilitic cases without mercury, but experience soon showed him that this practice was erroneous, and he has ever since abandoned it, and he has never had any occasion to regret the change. His mode of administering mercury is in a mixture containing corrosive sublimate dissolved in a solution of iodide of potassium, the dose being at first small, and gradually increased, and continued for several months, but without affecting the system injuriously. He believes that the beneficial effects of the mercury are secured by this mode of administration, while any unfavourable results are obviated.

One of the lectures is devoted to the subject of Syphilisation, of which Dr. Hammond speaks in disparaging terms. The principle of syphilisation, indeed, is entirely at variance with the views as to the nature of syphilis maintained by Dr. Hammond, and with the doctrine of the duality of the venereal poison. Dr. Hammond admits that the matter of the soft chancre may be successfully inoculated, but he argues that the operation is unnecessary, because soft chancre is not followed by constitutional effects; and he denies that the matter of the indurated chancre can be inoculated on the same individual, and although it may be inoculated on another individual, such a proceeding is propagating the very disease which syphilisation professes to prevent. Such are briefly the opinions expressed by Dr. Hammond on a subject which is now engaging very great and deserved attention, and the investigation of which is likely to lead to important results. We may remark that the general performance of syphilisation with a view to curing syphilis cannot be advocated except by those who maintain the unity of the syphilitic virus.

In reference to the pathology of gonorrhœa, and its origination from chancre, Dr. Hammond adduces a number of cases which seem to favour this view. The subject is a very difficult one, and its investigation is surrounded by many sources of fallacy, but Dr. Hammond is a very careful observer, and we are bound to receive his statements of cases with the credence due to his accuracy and good faith. But while arguing that syphilis and gonorrhœa have a common origin, and that a chancre may by infection cause either a chancre or a gonorrhœa, he recommends that each should receive a specific mode of treatment, that for gonorrhœa consisting chiefly of weak astringent injections. Dr. Hammond does not think that copaiba and cubebs have much power in controlling the disease, but the former he considers the more efficacious of the two.

From the above brief review of Dr. Hammond's work, it will be seen that it touches on many points of very great interest, and we cordially recommend it to the notice of the Profession.

A Practical Essay on the Use of the Nitrate of Silver in the Treatment of Inflammation, Wounds, and Ulcers. By John Higginbottom, F.R.S., Hon. F.R.C.S. Third Edition much improved, pp. 172. London: Churchill and Sons. 1865.

There are few persons in the Profession who are not aware that the use of nitrate of silver in surgery has been very much promoted and extended by the researches and the writings of Mr. Higginbottom, and the appearance of his essay in its present improved form will be a welcome addition to the shelves of the Medical library. The author's attention was directed to the use of this salt in surgery upwards of forty years ago, in consequence of a trial of its efficacy in the cure of an irritable and inflamed sore on his own finger, and he was led to investigate its properties with a view of rendering its application more extensive than it was before the period referred to. The first essay on the use of the nitrate was published by Mr. Higginbottom in 1826, under the title of "An Essay on the Application of the Lunar Caustic in the Treatment of certain Wounds and Ulcers," and finding that it was a very valuable agent in arresting and subduing external inflammation, he issued a second edition three years afterwards. The term "Lunar Caustic" was abandoned because the salt possesses a conservative rather than a caustic property. Thirty-six years have elapsed since the second edition of the essay was published, and Mr. Higginbottom conceives that a third edition is now required, in which his extended experience may be made

known to the Profession, and in which the papers scattered throughout different Medical and surgical periodicals may be brought together.

The use of the nitrate of silver is at present so extensive among surgeons, and its value is so fully appreciated, that it is unnecessary for us to enter at length into Mr. Higginbottom's arguments in its favour, or to comment on the cases he records in which it has been successfully employed. Mr. Higginbottom tells us that the various impediments to the free use of the nitrate have been a source of continual trouble and annoyance to him ever since the second edition of the work; but he thinks that they have arisen from erroneous views, promulgated by different lecturers and authors, totally at variance with the plain directions and principles laid down by himself. The impediments, in his opinion, have been five-fold, namely, the supposed caustic quality of the nitrate, the suspicion of its causing metastasis to the internal organs, the deviations from Mr. Higginbottom's method of applying the salt, the varying strength of the solutions employed, and the use of a new and worthless preparation. All these objections are combated by the author with great force in the present essay.

It is probable that in the present day the nitrate of silver, after being too much neglected, has arrived at its fair appreciation as a remedial agent, and that its mode of application is pretty generally known; but the monograph of Mr. Higginbottom will be advantageously consulted by all those who desire to know how its reputation was acquired, and how its efficacy in certain forms of inflammation, wounds, and ulcers may be best secured.

The Personal Responsibility of the Insane. By James F. Duncan, M.D., T.C.D. Pp. 98. Dublin: Fannin and Co. 1865.

Dr. Duncan states in his preface that this work is intended rather as a popular essay than a regular scientific treatise; but it contains a great amount of sound reasoning upon some very difficult topics, and it will repay the time spent on its perusal, whether the reader be a scientific person or not. Starting with the question whether there is any real difference between insanity and crime, Dr. Duncan resolves it in the affirmative, defining insanity as a morbid condition of some part of the material organisation connected with the mind, while crime is a perverted action of the mind itself. "The one," he says, "is properly a disease, and belongs to the province of the physician: the other is a change independent of disease, and belongs to the province of the moralist." P. 9. This distinction is specious enough, and if its truth could be demonstrated, the boundaries between insanity and crime would be defined with sufficient accuracy to satisfy the mind even of a common juryman; but unfortunately the "morbid condition of the material organisation" cannot be shown by any methods known to the pathologist, and except in certain exceptional cases, the brains of lunatics have not exhibited, after death, any appearances which could reasonably be supposed to account for the mental aberration during life. Indeed, on perusing Dr. Duncan's book, we fail to discover, even on his own showing, what the material morbid conditions are to which he attributes insanity, and we think that he himself confounds together structural and *functional* disturbance of the encephalon. Now, if insanity may be due to a functional disturbance of the brain, where is the demonstrable difference between it and a change independent of disease? We do not deny the propriety of Dr. Duncan's definitions, but in a book intended as a popular essay, it would have been as well to point out the method of drawing the distinction. We have heard that the dictum has been uttered from the bench that insanity can only be proved by the presence of physical disease, as inflammation, congestion, injury, &c.; but as such proof cannot be given in ninety-nine out of a hundred cases of insanity, the opinion is worthless. Dr. Duncan does not entertain this opinion himself, and yet his statements are calculated to lead the general public to believe so.

Passing on to investigate the question of the personal responsibility of the insane, Dr. Duncan admits the existence of partial insanity, and would therefore argue for a partial or limited responsibility, and he almost advocates the propriety of a partial or modified punishment in such cases. He would, even, in the case of suicide, endeavour to dissuade the living from committing such an act by devising some modified form of unchristian sepulture for those who have died by their own hand, unless in clear cases of positive mental derangement.

We have thus alluded to a few of the topics touched upon in Dr. Duncan's essay, which, as we have stated, contains a great amount of sound reasoning, and although, of course, on such a difficult theme, many will differ in opinion from the author, yet none will fail to perceive that the sentiments expressed are those of an accomplished scholar, an able reasoner, and a judicious practitioner.

EXTRACT FROM AN
INTRODUCTORY LECTURE,
AT

THE ARMY MEDICAL SCHOOL.

Delivered at Netley on October 3rd, 1865,
By Deputy Inspector-General T. LONGMORE, Professor of Military Surgery.

In welcoming you to the Army Medical School, let me beg of you to dismiss from your minds the prejudiced remarks which are put forth from time to time respecting your being kept at school notwithstanding you are holding licences for practices from colleges and universities; and let me ask you to wait until you know by experience what the nature of the work done here is, and can form for yourselves a fair idea of its probable value to you in the career you have selected, before you allow such notions to have any influence on your minds. Such disparaging remarks are, of course, made for the purpose of deterring professional men from competing for appointments in the Medical service of the army; but, as far as I know, they have only been made by persons practically unacquainted with the school, who allow their own conceptions to take the place of knowledge of the work which is really done, and who build upon this false foundation an equally false and untenable superstructure; and generally also by persons who are impressed with the notion that the duties of a military surgeon do not differ from those of practitioners in civil life. I have never known such remarks made by anyone who had gone through the course of instruction here; but, on the contrary, I have constantly heard at the close of sessions, and that, too, from candidates who have been distinguished for the zeal with which they have taken advantage of the opportunities afforded them, expressions of regret that those opportunities have been of such short duration. Wait, then, I say, till the end of the session, and then form your own opinions, and place no dependence on those of others. Even some who have been employed in the duties of the hospital, in connection with which the school is placed, go away with but imperfect notions of the work which is done in it, because they do not frequent the lecture-room or demonstrations in the post-mortem theatre, nor care to benefit by the splendid opportunities of improvement in hygienic and microscopical investigations and the other studies which may be pursued here with so much advantage. Some, on the other hand, and generally those who in the first instance are the most able officers, take advantage of all occasions of improvement which their occupations allow, and these alone can fairly estimate the advantages afforded to you by her Majesty's Government in this establishment. I and many others who received commissions in the Army Medical Service at a time when no such school existed, are able fully to appreciate its importance, and can honestly testify to its value from our own experience of the want at starting on our duties of much of the information which you are now enabled to obtain so easily.

It would be mere labour of repetition, were I to take up your time with an account of the history of the Army Medical School, the causes and considerations which led to its establishment, the system on which it is constituted, or

the purposes aimed at in the constitution so given. You may find full particulars on these matters in the Warrant issued by the Secretary of State for War in March, 1860, and in the introductory lecture delivered at the opening of the school in presence of the lamented Lord Herbert, who took so active a part in its foundation. The lecture, and Lord Herbert's address on that occasion, are printed in the first of the published volumes of the Army Medical Reports. I recommend you to peruse them, as they will probably enable you to understand your position and liabilities while you remain under the direct authority of the School Senate better than you may otherwise do.

Neither do I propose to lay before you any systematic exposition of the work you will be engaged in during the coming session. Each professor, in the opening lecture of his course, will explain the special objects of his department, and the plan on which they are to be pursued. In addition to this programme, it will be my duty to explain to you at starting the general system of organisation given to the Army Medical Department, for admission into which you are now candidates, and into which it must be your own fault if you do not enter at the close of the session—its relations to all the other departments of the military service—the plan on which military hospitals, including regimental hospitals and general hospitals, such as this, the Royal Victoria Hospital, are ordered to be carried on; the functions of those in whom rest the military command and responsibility for discipline and order of the whole establishment, and of those in whom the professional direction is vested, as well as to explain to you the nature of the multifarious duties—professional, sanitary, and statistical—which will hereafter devolve on you as Medical officers in the public service. I will, therefore, not further refer to these matters beyond saying that hereafter you must not forget you are now voluntarily entering an establishment, and adopting for your career in life a service which has been systematically organised by the highest authorities of the realm, and that any unsanctioned departure from its established rules will certainly lead to trouble as regards the individuals attempting to set them aside, as well as to interruption of that co-operation of different official departments, and steady progress of the train of public business which the regulations have been designed to ensure.

There is one part of our future work which I wish to say a few words upon, and that is the clinical instruction which will be given by the professors and assistant-professors in the wards of the hospital. Some whom I am addressing have, doubtless, been dressers or clinical clerks in civil hospitals, or perhaps assistants to gentlemen in private practice, and have thus become acquainted with the actual features of certain examples of disease and injury, and practically acquainted with their discrimination. But some others, and, as we have found by experience, not a few among those who have come here hitherto, have had no such advantages, or have had them only to a very limited extent. Not having obtained any insight into the features of disease before proceeding to attend the courses of instruction at the established Medical schools, such as was formerly acquired when the system of apprenticeship existed, and, at the hospitals to which the schools are attached, having been confined to looking on the patients from a distance, as it were, to hearing the casual intermitting remarks of surgeons and physicians as they went round the wards to visit their patients, without having any active concern in their care or treatment,—"walking the hospitals,"—they have come here with only that theoretical information and those crude general notions of diagnosis and therapeutics which entail, as a necessary result, endless unexpected doubts and difficulties when they are first applied to the actual work of practice. Some gentlemen have told me that they have never had a patient under their care and treatment before they came to Netley, have never even been called upon practically to diagnose a case of disease or injury until they were required to do so in their competitive examination in London. They have never had to watch the course of a disease through its varying phases, to appreciate its modifications of form and character according to age, habits, and constitution, or to feel the responsibility of its treatment, during the whole of their professional education. What wonder, then, that those who are practically unacquainted with the shades of distinction which require to be so carefully observed in order to determine differences in type of disease, who have never felt the necessity of the close and careful observation which is frequently required to decide with exactness upon the results of injury to some intricate portion of the human frame,—what wonder that they should occasionally make the most startling mistakes in diagnosis, the most faulty suggestions as to practice, when they are first brought into contact with disabled patients! I know that in some hospitals steps are being taken to insure that every student shall have a certain share of Medical and surgical practice by introducing a polyclinic system, such as was so strongly advocated by Sir James Clark many years ago in his published writings; but it is yet far from being as general as circumstances have shown it desirable that it should be.

The clinical teachers of this hospital are placed in a position in which no other persons in the kingdom, perhaps, are placed as regards opportunities of observing the attainments of those who are just launched from professional training into professional practice. Gentlemen who have recently received licences to practise from authorised bodies established in all parts of the three great divisions of the kingdom, are gathered together here. The teachers have to watch the manner in which these gentlemen deal practically with the treatment of disease; to observe their qualifications for the discharge of those professional duties the right performance of which has been the ultimate object of their education. They ascertain their amount of real knowledge of the human frame, its conformation, and the effects of injuries and diseases upon it, not by word-of-mouth examination, but by their manner of proceeding to deal with the very things themselves. Now, while it is a pleasure to observe the practised dexterity of some, and their acquaintance with the right methods of arriving at sound conclusions as to the nature of the cases placed under their charge, I should be telling only part of the truth if I were not to add that it is occasionally a subject of surprise that others should be so completely adrift, so unable to distinguish common conditions of disease or effects of injuries, and so ignorant of the common manipulations necessary amongst the patients in the Medical and surgical wards as they have shown themselves to be. Instances have occurred where it has been almost impossible to understand how the colleges which had presented those concerned with their licences could have passed them as qualified, what tests they applied to ascertain their fitness for practice. And these gentlemen who caused these impressions must have been considerably superior to others who had passed into civil practice; for, in competing for their appointments, they had left others behind who had not been considered admissible. The same absence of practical knowledge has been from time to time exhibited in the post-mortem examination-room. The manner of proceeding even to open the body for the display of its cavities and their contents, still more of investigating or expounding their condition, has been quite strange to some; they had never had the operation to perform. There must be something bad in the system of teaching at those places where such instances of deficiency come; and it is a serious matter for those to whom the regulation of professional education is entrusted to consider what must be occasioned by the consequences of authorising for practice persons unacquainted with the practical work of their Profession. I am well aware that experience can only be attained in years; that under any system of education the experience of those who have recently received licences of practice must be inferior to that of others who have had opportunities of extensive observation; but it is to be remembered that in the remarks I have been making I have referred to the difference in attainments which has been exhibited amongst men of about the same professional standing as to years, and that there is little reason to doubt that therefore, if some amongst them, under one system of education, have gained solidly practical knowledge, others

who have been so deficient as I have mentioned, might equally have gained it under a like system.

Do not let me be misunderstood when I make these remarks. They are applicable only to exceptional instances which have come to notice. The attempts which have been publicly made to deprecate universally, without distinction, the attainments of the gentlemen who have been of late entering the Medical service of the army, by stigmatising them as third-class students, for the sake of achieving certain objects of general policy, has been most unfair and unworthy. At all events, every gentleman who has entered the public service has passed through a competitive examination, which others had tried to do and failed in, and which probably more had thought fit not to face from a consciousness of probability of failure. Those who have published such charges should inspect their own ranks, for it may fairly be presumed that the candidates who have not succeeded at the competitive examinations have passed into civil practice. The division into three classes of those who passed through the competitive examination in London have the opportunity for this erroneous stigma being propagated. This classification really corresponded with the separation into classes of those who have undergone an examination for honours in a university. But it was interpreted by those who did not understand it, or did not choose to understand it, to signify the general attainments of those concerned—to comprehend degrees of comparison with the whole of the passed students of Great Britain. Those who were in the third of these three classes were publicly called students of third-rate ability. As well might a Master of Arts who had come out in the second-class in the competition for classical honours at Oxford be stamped for life as a man of second-rate ability. Unfounded, however, as the assumption was, on which the appelation of third-class students was given to those who were entering the Medical Department of the Army, it had an injurious effect among many who were not acquainted with the circumstances whence it sprang, and was a source of pain to those whom it was applied. Hence it became necessary, in order to prevent this abuse of terms, to abandon the division into classes of those who had successfully passed through the competitive examination in London, and to arrange the list of names simply according to order of merit, as is done in all other army competitive examinations.

I will refer to one other topic which, though not forming part of our work here, has an important bearing on it. I allude to the subject of general education. We have a few instances in which there has been such a deficency in some branches in general education—even in knowledge of grammar, spelling, and the meaning of ordinary English terms—as to threaten to lessen materially the usefulness of those concerned in the public service. It is not part of the duties of the examiners for the Medical Department of the army either in London or here, to inquire into general education: professional qualifications are the subject of their inquiries. But even here a knowledge of the right signification of words, and of their proper arrangement in composition, becomes important. Want of it causes, on the one hand, frequent misapprehension of the language used in the lecture-room, and, on the other, leads to unintentional and often serious errors in professional documents. The absence of rightly selected terms and expressions, as well as of care in the grammatical construction of sentences, is a frequent source of difficulty to the examiners when they are trying to determine the amount of professional knowledge possessed by the writer of some particular paper under examination. But it is not only in the examination papers that this defective composition creates difficulties: it actually forces itself upon the attention while inspecting the records made of the histories, symptoms, and progress of diseases in the Case-books. Not only scrupulous rectitude in observations of the minutest details of facts, but also equal accuracy in the expressions employed to record them, are absolutely essential to give to scientific records the stamp of truth. To form a just exposition of a case of disease or injury, or to give a fair reply to a question proposed for the purpose of testing professional acquirements, there should be, in the first place, a correct knowledge and appreciation of the facts involved, then an orderly arrangenent of them in the mind; and, lastly, appropriate language for their description. The extreme importance of attention to literary truth and exactitude in a professional career is hardly, I think, sufficiently estimated by Medical observers and practitioners in general. It appears to me that, in the test of general education which is now required before the study of the Medical Profession can be regularly commenced, more particular inquiries should be made on this subject than are evidently occasionally instituted. I would not ask for any fine writing, but I would consider it an essential ingredient of fitness for commencing the study of Medicine, that the student should demonstrate that he thoroughly understands, and is able to write, plain English. Let me urge those among you who are now preparing for a career in the public service, if you wish to attain eminence in it not to neglect the cultivation of exactness in language.

There is one other aspect in which this matter may be regarded. It is by the *general* education of an individual that non-professional persons are apt to estimate the amount of his professional education. Now, where so much depends upon the persons among whom a Medical practitioner exercises his Profession having confidence in his ability and judgment, it is essential that nothing should be neglected which is calculated to create a favourable impression regarding these qualities. I see it argued in some professional publications that it is injudicious to insist on a liberal general education for Medical practitioners, for Medical men would not be found to attend upon the poor if it were so. This I believe to be a libel on our Profession. We see clergymen of liberal education visiting the poor in all districts, and receiving them into their houses for instruction and advice; and there seems to me no more difficulty in supposing that Medical men of liberal education would do the same, than there is in understanding why, under present circumstances, the curate, however limited his income, or however pauperized the sphere of his avocations may be, usually takes a higher social status than that of his Medical neighbour. But in the army, at any rate, it is essential, if Medical officers intend to maintain the dignity of their Profession, and to gain personal respect, that they should be the equals of their brother officers in general education. It is not now as it was formerly with combatant officers, when no test of general education was required before commissions were conferred—when ignorance was often overlooked in favour of interest; all combatants are now required to give proofs of possessing a good general education, and some of a fair knowledge of the natural sciences, before they can hope to obtain a commission in the public service. If the Medical officers are to preserve their old distinction of being the men of education and science in the ranks of the army, they must not rest passive, but must exert themselves to advance in the race proportionably with the progress of their neighbours.

I have not been exposing to you the brighter aspects of our school affairs. It would have been more agreeable to have looked only at those portions of our work and its progress which are all that can be desired; but it is more profitable to notice and consider the defects which are made apparent from time to time, with the object of effecting their removal, or at least their improvement. I have been trying in the short space of this lecture to offer some advice to those who are commencing their preparations for the practice of their Profession in the army, which may be useful in clearing away impediments to their future usefulness, if not distinction. We have reason to know that great good has been gathered by some who have attended this school, and that the good seed gathered is now being sown far and wide, increasing and multiplying. To urge on and improve the work we must weed as well as plant. And I trust I have not been speaking to anyone whose object in entering the public service is merely to confine himself to the narrow limits of just getting through its necessary duties; who is not animated by ambition of continuing to improve himself, and to do as much good to others as his future opportunities will allow; and who is not prepared

and desirous of personally exerting himself to achieve these worthy objects. Even the honours which are now to be gained in the Army Medical Service should act as incentives to such exertions, even if higher motives did not exist. Look at the distinctions which have been won and conferred on the surgeons and assistant-surgeons lately in New Zealand; honours have been more liberally bestowed there in proportion to the numbers employed than they have ever been in any previous campaign.

YELLOW FEVER AT SWANSEA.

The following letter, from J. Rose Cormack, M.D., F.R.S.E., "On the Nature of the 'Yellow' Fever now at Swansea," has appeared in the 'British Medical Journal.' Dr. Cormack is well qualified to write on the subject as he is the author of one of the best monographs on fever which has appeared in late years:—

SIR,—"Yellow fever at Swansea!" is an alarming announcement, the truthfulness of which will, I trust, be explained, as well as admitted, before the opportunity for minute inquiry and observation shall have passed away. Let it be granted, that the announcement referred to has been made on reliable data by last week's newspapers and Medical journals; still the public may, I think, be instructed to regard the intelligence very calmly, if they look at it in the light of Medical history and epidemiological experience. It will then most probably be admitted that there is no ground for alarm at the supposed invasion of a foreign pestilence, but much cause of thankfulness for a mild warning to the municipal authorities of many of our towns, as yet unprepared for the advent of disease likely to take root and spread under the favouring influence of famine, filth, or suc exceptional atmospheric condition as have lately existed.

Twenty-two years ago, at the close of summer, a contagious fever broke out in the slums of Edinburgh, Glasgow, Dundee, and other Scottish towns. Early in the hot September of that year, 1843, the fever being then at its worst in Edinburgh, in addition to the provision for fever cases in the Infirmary, a new Fever Hospital was opened with eighty beds, and placed under my charge. In the December of that year, after careful observation and reporting of hundreds of cases, I published an account of my personal knowledge of that memorable epidemic, giving the minute history of a sufficient number of cases to illustrate the different forms of the disease. From what I have since read, and from what I have since seen, at home and abroad, of fever, I cannot help thinking it very probable that the language in which I described the "highly congestive form" of the Edinburgh fever of 1843 may be found descriptive of the Swansea cases now so properly attracting the notice of the Medical Department of the Privy Council.

In the work referred to, I said: "One of the most common symptoms in the highly congestive form of the disease is yellowness of the conjunctivæ, and of the whole surface of the body. It generally appears between the third and seventh days, and is always most intense on the face, neck, chest, abdomen, and thighs. The hue of the neck and chest is the most vivid. . . . Associated with the yellowness, there are generally depression, less or more delirium, ... and hæmorrhages from some of the mucous membranes. In the worst cases, black coffee-ground-like matter is ejected. In some cases the black vomit occurs without the yellowness; and, on the other hand, at the autopsy of yellow patients who have had no black vomit, this matter has been found in the stomach and other parts of the alimentary canal." Such were many of the cases of the Edinburgh "relapsing" fever of 1843, treated by me immediately and for some weeks after my appointment to the Fever Hospital. The weather was then hot; and the cases, for want of hospital accommodation, had been accumulating in overcrowded and dirty lodging-houses. As the season advanced, the temperature fell, and vigorous house-cleansing was adopted. Under these altered conditions, the yellow cases disappeared, though the "relapsing" fever continued for a long time to prevail in a milder form. Are not the Swansea yellow cases of the hot September of 1865 similar to the Edinburgh yellow cases of the hot September of 1843?

Till the facts have been placed before the public in a more detailed and unimpeachable form than that in which they have yet been published, it would, of course, be premature to give a positive opinion as to the nature and origin of the present Swansea fever. It is, however, very important, at this stage of the inquiry—while yet there is an opportunity of observing, and at once writing down what is seen—to express a hope that the Medical Profession of Swansea, and the Medical Department of the Privy Council, will rigidly take and fully publish evidence, not only as to all the circumstances connected with the state of health of the crew of the 'Hecla' during her voyage from Cuba and on her arrival at Swansea, not only regarding the intercourse between her and the Swansea residents attacked with fever, but likewise as to *the type of fever and all diseases in Swansea at the date of the 'Hecla's' arrival, and for months before and subsequently to that date.* Has disease exhibited a more than usually marked intermittent or remittent type? Have there been cases of ordinary relapsing or of other fever? This latter inquiry is specially important; and no inquiry will be complete till the questions have been clearly settled in the affirmative or negative. The yellow cases which ocurred in Edinburgh and other Scottish towns in 1843 truly belonged to the same epidemic of "relapsing" fever in which the majority of cases were not yellow. As the skin is sometimes very yellow in cases of typhoid fever, a yellow skin must not be taken as a test by which to determine the nature of a fever.

I beg to recall attention to the fact that the Scottish epidemic of 1843 was not supposed to be of foreign origin; that it almost simultaneously sprang up in several towns; and that it originated among crowds of dirty Irish reapers and others huddled together with them in localities always overcrowded and ill-ventilated, and then far more closely packed than usual. Filth, overcrowding, and deficiency of air, combined with the high temperature of the season, no doubt stamped the fever with an aggravated type; though it is not so certain, as some have maintained, that it originated in these conditions. While it spread like a conflagration from top to bottom of the lofty "lands" of the High street of Edinburgh, scourged the adjacent closes, and reigned for months triumphant in the low lodging-houses of the Grass-market, Cowgate, and West Port, it did not cross the bridges to the New Town. A few scattered cases which did occur there, were all clearly traceable to much contact with congregated sick in the Old Town. In the other Scottish towns visited by the epidemic, the exemption of the districts under good sanitary conditions and inhabited by better classes was as well marked as in Edinburgh.

Taking, therefore, into account all the circumstances as at present before the public, the announcement of yellow fever being at Swansea, truthful though it be, is not very alarming. It ought, however, to be accepted by the municipal authorities of that and other towns as a warning to conform to Nature's laws of health, which cannot continuously be infringed with impunity. Without solving the scientific question, What constitutes yellow fever? it can be truly said, that the terrible disease known by that name in the tropics has never established itself in the British Isles, though in numerous instances, ships with cases on board have come into our ports. It ought to be reassuring to the public to know that the real "yellow Jack" cannot multiply in our temperate climate; and that it is only in unventilated ships and hovels, amid rotten vegetation, and excessive humidity, in countries with a mean temperature of 82 deg. Fahrenheit, that the scourge has prevailed.

In conclusion, let me add, that the chief object of this letter is to express a conviction that such inquiries as that now going on at Swansea lose more than half their value when not carried out with extreme rigour, on a very broad basis, and over a considerable space of time. The value of much that has been recently well written on particular epidemics, is impaired by the narrow area within which information has been gathered. The history of an epidemic is very disappointing to the student of epidemiology, when it only describes well marked cases, and fails to give the characteristic features of all contemporaneous disease.

CHOLERA AND THE WATER OF PARIS.

In connection with this outbreak of disease in Paris, a listinguished French Physician, Dr. Vacher, has been aving a dispute with the municipal authorities respecting he water supply of the city. Dr. Vacher has been to Eng- and lately, and has made himself master of the remark- ible series of facts that have accumulated here since the ime when Snow first brought out his immortal investiga- ions respecting the propagation of cholera through the nedium of water. Returning to Paris, Dr. Vacher applied o the head engineer of the Paris waterworks to be allowed o take samples of the water from the reservoirs that he night examine them for organic impurity. The authori- ies indignantly refused, alleging that in 1832 a report was urrent amongst the population, during the presence of the holeraic epidemic, that the waters were intentionally oisoned, and much mischief ensued from this preposterous umour. On receipt of this refusal, Dr. Vacher wrote a etter to the 'Temps,' in which he said that he had written ourteously to the Administration, and had asked respect- ally for what was the right of every person who paid taxes. Iis desire was, that in Paris there should be issued every nonth analyses of the water-supply like those for London egularly prepared for several years past by Professor ofmann. He also quoted from Bouchut to show that at èvres diarrhœa frequently becomes epidemic amongst ose who drink the water of the Seine, but immediately opped in those who substituted for the river-water that om an artesian well. He denied an insinuation that had een thrown out against him by the authorities to the fect that, in his opinion, the few cases of cholera that had curred in Paris were due to intentional poisoning of the ater; but he held that the water was poisoned *by organic atter*. Here the subject rests.

We may add, in support of Dr. Vacher, that the epidemic Paris of 1832 was evidently spread almost exclusively means of water. The poorer people, therefore, guided turally and inevitably by daily observation, attributed— d rightly too—the malady to poison in the water. The istake they made was, that in their ignorance as to the ssibility of accidental introduction of organic poison, they me to the false conclusion that ordinary poisons had been troduced intentionally, an hypothesis that was favoured the political excitement of the time.

Before leaving the question of cholera in Paris, we must t omit to mention a noble instance of self-sacrifice on the rt of our brother-Professionals in that city. A consider- e number of these philanthropists have waited upon the nister of Public Works, offering their services for any he towns at the present time infected by the disease. rtunately the reply was, that such services were not at sent needed, but that they would be gratefully accepted hey should be required in the future.

At Marseilles and Nimes the epidemic is disappearing, at Arles it was on the increase, and was causing many ths. At Toulon, the malady was fluctuating, but on ober 4, out of 26 deaths, 14 only were reported as from lera. On the same day (October 4) at Marseilles, out of deaths, 11 were from cholera; from the 1st to the 7th, total deaths from all causes were 264, of which 91 were n cholera, showing an increase of deaths from cholera the preceding seven days of 25. Dr. Honnoraty had en a victim to the malady, owing to his excessive ours amongst the afflicted poor. His death created the foundest regret. At Arles, on the 4th, there were 11 ths, of which 8 were from cholera; and at Nimes, 2 ths were from cholera. On the 8th, there were only 8 ths at Marseilles from the epidemic, at Toulon 7, and at Seyne 2.—'Med. Times and Gazette.'

PIUM SALES AT CALCUTTA.—At the last Calcutta opium each chest fetched 104*l.*, a largely increased price owing he diminution of the supply.

IRENCESTER HOSPITAL AND INVALID KITCHEN.—It is posed to establish an hospital in Cirencester, to which is e added an establishment for training nurses, and an alid kitchen.

GENERAL CORRESPONDENCE.

THE TREATMENT OF CHOLERA.

To the Editor of the Medical Circular.

SIR,—I have observed, in the MEDICAL CIRCULAR of the 20th ultimo, an article by Thos. R. Torbock, M.D., purporting to be a brief sketch of cholera, as it first appeared in the town of Sunderland in the years 1831-2, and causing at that time most frightful panic and alarm amongst the people. It is somewhat remarkable, however, that while the Doctor informs us that several *post-mortem* examinations and analyses of the blood were conducted by himself, Drs. Clanns and Miller, and that the pathological signs and appearances fully substantiated their previous convictions of the disease being the real Asiatic cholera, yet he neither lets us know what led them to those convictions, nor what really were the pathological signs or *post-mortem* appearances on a single one of his cholera patients. And with regard to the proper treatment of cholera, although Dr. T. R. Torbock informs us that the government officials of those days were quite at sea on that point, he omits to let us know anything of the nature or *modus operandi* of his own treatment of the disease, notwithstanding that it had been very successful—so far, at least, as the Doctor himself has informed us. Some recommend, he tells us, spirits of turpentine, laudanum, and mucilage, in draughts to be taken every two hours, others, as David Barry of St. Petersburg, would only recommend a solution of common salts, and in extreme cases the actual cautery to be run down the spine, while the sheet anchor of Dr. Gibson was extensive blood-letting; and of late days a certain Doctor (Chapman) has informed us that there is no remedy at all equal to the spinal ice-bag for any real case of cholera or diarrhœa. A Dr. Dann suggested castor oil and sulphate of magnesia, but we all know, as well as Dr. Torbock, that neither castor oil, sulphate of magnesia, nor even the spirits of turpentine would be at all likely to remain any time on the weak and loathing stomach of a poor cholera patient. But to place both calomel and laudanum along with, or in the same category as all the other vagaries (as he styles them) of those several Medical men, is rather too bad, in my opinion. I perfectly agree with Dr. Torbock, however, in thinking that neither the ejecta nor excreta, nor cholera patients themselves, are by any means infectious, as I have been very often myself much exposed to, and brought in contact with, many such cases in the town of Antrim in the years 1854-5, and yet never was the least affected by any of them—thanks to Providence.

But while Dr. Torbock goes on thus to condemn and ridicule the *mal practice* of other Medical men, he seems to me to have entirely forgotten himself and the old adage—viz., that when we speak of the *dead*, we ought to tread softly over their graves. With all due respect, however, towards Dr. T. R. Torbock,

I am, &c.,
NEIL MCGREEVY L.R.C.S. Edin., &c., &c.

Drogheda, October 5th, 1865.

P.S.—The spirits of turpentine (although no doubt a most useful remedy as an external application in puerperal peritonitis or such like) I have not found to be so in cholera, as I have found many poor cholera patients who could not endure even the *smell* of *it* in the room where they were; so I found a good strong *mustard poultice* to answer much better as an external application in most cases of real cholera. —N. McG.

VACCINATION AND SYPHILIS.—This highly important subject has been fully treated by the 'Siglo Medico, a Spanish Medical paper. In this article we find statistical tables of some value. The author, in collecting data respecting the instances of syphilitic contamination through the vaccine virus, has been led to draw up a table which shows that the disease was communicated 224 times out of 314 vaccinations. It should be noticed that the 93 negative cases were such as evidently *might* have conveyed the complaint.

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 18, 1865.

MEDICINE NO MYSTERY: DOCTORS NO DOGMATISTS.

We have lately had occasion to remark with some severity upon a very silly leading article upon the Medical Profession in the columns of the 'Times,' which effusion would be beneath contempt except for the medium which gave it publicity. It would have been discreditable even if it had appeared in one of the penny papers, on which the Jupiter of the press often bestows some severe and not unmerited castigation, on account of their arrogance and ignorance, and their subservience to the lowest prejudices and passions of the multitude. The more difficult the subject treated, the more flippant and supercilious are the commentaries made by these pretended instructors of the masses, who often boldly decide questions which have puzzled the most able philosophers; and as these sensation-leader writers moreover despise everything that they cannot understand, the field of their vituperation naturally extends over almost a boundless space. But in the columns of the 'Times' something better might have been expected, and at least it would be supposed that a writer in that Journal possessed some elementary knowledge of the subject which he was allowed to treat.

But putting the article in question aside as undeserving of further notice, it is not an unprofitable duty to ask ourselves what are our real pretensions to public support, and what is the actual position of the Medical Profession in its relation to science on the one hand, and to the well-being of the community on the other. In the first place, we may observe that Medicine is not itself a science, as some persons have erroneously supposed, but an art built upon a foundation of many sciences, as anatomy, chemistry, physiology, natural history, all of which are sciences in the true sense of the term. Anatomy, for instanee, presents certain data which are incontrovertible, such as the number of the human vertebræ, the structure of the teeth, the mechanism of the eye, and so forth; and many of the axioms of physiology are equally indisputable, such as the heart being the chief organ of the circulation, the eye being the instrument of sight, or the ear that of hearing. But Medicine is capable of announcing no such facts as indisputable truths, and the most it professes to do is to express certain general conclusions derived from experience, and liable to variation as circumstances change. The relation of cause and effect, either in the origination of diseases or in the operation of remedies, although it may often be surmised, can hardly ever be logically proved, because the fallacies surrounding our observations are necessarily very numerous, and because the constitutions of patients are infinitely varied.

To assume that there is anything of mystery in the practice of Medicine is utterly absurd; there is no mystery at all. All that is required of the student of Medicine is that he should begin by possessing some knowledge of the sciences on which Medicine and Surgery are founded; and this knowledge, like any other, can only be acquired by study and practice. To make Medicine a popular pursuit, or to teach every man to be his own doctor, would be a vain attempt, not because the necessary knowledge is unattainable by ordinary tellects, but because practice and training are necessary in this as in every other department of skilled labour. To suppose, too, that a person may qualify himself for Medicine or Surgery, or even for criticising the practice of Medicine and Surgery, by poring over books, however excellent, is an equally fallacious idea, because books are good only as they are the exponents or interpreters of facts, and those facts must be observed by the student himself. All our hospitals present an assemblage of facts, which may be learned by all who possess the requisite preliminary knowledge, and which may be classified, arranged, and utilised by all who, in addition to knowledge, have adequate reasoning powers.

As there is no mystery in Medicine, neither is there any dogmatism; the latter must be looked for among the pretensions of quackery. Medicine does not assert that it possesses infallible cures for all or any maladies, nor does it even pretend to determine exactly how drugs and regimen operate at all. It may, indeed, offer plausible explanations as to the *modus operandi* of this or that remedy, but it does not insist that such views are to be universally accepted, nor does it impose the slightest limit, except that of reason and common sense, upon the expression of opinions by any independent observers. People may or may not believe that colchicum eliminates the poison of rheumatism, and practitioners are fully at liberty to treat that disease in any manner they think most advisable; and they may starve or feed inflammations according to the indications presented by the constitution of the patients. Medicine no where asserts that diseases are cured by agents which are antagonistic to the supposed essence of the diseases, simply because it does not know what the essence of disease is. This ignorance is no more a reproach to Medicine than ignorance of the electrical condition of the air which produces storms would be a reproach to navigation. The physician does what he can to allay the storm in the human system which constitutes disease, and the mariner navigates his vessel as well as he can through the storm of the elements; but how or why either storm originates it is at present, and probably ever will be, beyond human power to determine.

Not so, however, with quackery, which really does dogmatically assert certain principles and makes them the bases of its faith and practice. The homœopathic quackery, for instance, asserts that diseases are removed by remedies which themselves would produce the diseases they are given to cure; but this dogma is wholly gratuitous, and is not only unsupported by experience, but is contradicted by a multitude of facts. The law, or supposed law, is founded upon a fallacy, and is therefore untenable. The other proposition of homœopathy is still more absurd, because it is

posed to physical laws, namely, the assertion that the effi-
y of medicines is in the inverse ratio to the dose in which
ey are given. It needs no argument to show that this
ory is as incapable of rational belief as that water is frozen
heat, and vaporised by cold, or any other similar paradox.
at patients sometimes recover under so-called homœo-
hic treatment is no argument whatever in favour of the
tem, because diseases will sometimes disappear spon-
eously, and a do-nothing or expectant treatment may
en be advisable.

Within the limits of reason, all practitioners of Medicine
free to entertain what opinions they please, or to prac-
e in the manner they think best; but when rational
ngs pin their faith upon principles inconsistent with the
rs of Nature, they cannot expect any sympathy from
entific men. As was happily observed in one of the in-
ductory lectures, an architect would not be trusted who,
building a bridge, would choose the lightest materials
bearing the heaviest pressure; so neither can we believe
at a disease can be removed by the administration of an
initesimal dose of inert material inappreciable by the
st delicate weights, and undiscoverable by the highest
wers of the microscope.

SUMMARY OF THE WEEK.

THE PROGRESS OF CHOLERA.

Without wishing in any manner to commit ourselves to
e expression of a dogmatic opinion upon so mysterious a
bject as the progress of cholera, we think that the chance
a severe invasion of that disease into the British Islands
ring the present year is but small. We do not intend to
ert that the state of the thermometer is an index to
ide us as to the rise or decline of the cholera epidemic,
t unquestionably its propagation is favoured by those
nospheric conditions which have prevailed to an unusual
ent during the late protracted summer, but which are
w, in the natural succession of the seasons, fast passing
ay. Though we do not doubt the genuineness of the cases
ich have occurred at Southampton and its neighbour-
od, and at Epping, yet the visitations have been confined
very limited localities, and, at Epping, almost to one
use. We deeply regret to confirm the report, that Mr.
Nab, a highly respected practitioner of the last-named
wn, has succumbed to the disease. While thus hoping
d believing that we shall be spared for a time from a
ere invasion of an epidemic which has been committing
h great ravages of late on the Continent of Europe, we
no means desire to lull the public into a false security, or
discourage the efforts which are being made to place our
untry in the best sanitary condition which it is possible
attain. On the contrary, we hope that the present warn-
will not have been given in vain, and that it will
mulate Boards of Guardians and other local authorities
take the most strenuous measures in the promotion of
se sanitary reforms which have been hitherto most
mefully, and, we might add, criminally neglected. If
xt year the unwelcome visitor should appear among us
all its terrors, the authorities who preside over our sani-
tary affairs will have to bear a heavy but just weight of
public indignation, if they longer delay the precautions
which prudence and science have repeatedly suggested.

MIDWIVES AND MAN-MIDWIVES.

A Dr. James Edmunds has been writing to the 'Times'
on Medical matters, and as his letter has for its object the
depreciation and injury of a large section of the Medical
Profession, it has, of course, been readily admitted into the
"valuable columns" of the leading Journal. Dr. Edmunds
has made the discovery that the lying-in patients attended
by the Royal Maternity Charity are subject to a smaller
mortality from puerperal diseases than the rest of the
lying-in women of the metropolis, and he therefore jumps at
the conclusion that the greater mortality is due to the fact
that the majority of lying-in women are attended by Medi-
cal men, and he consequently proposes that the practice of
obstetricy should be transferred to women. The fallacies
of the arguments and the statistics he employs it is almost
needless to expose, but we may observe that, although the
patients of the Royal Maternity Charity are attended by
midwives, the latter are under the immediate superintend-
ence of an efficient staff of physicians and surgeons; and
we may also observe, that the majority of lying-in women
in London are *not* attended by Medical men, *but* by mid-
wives. Dr. R. E. Swyer, who practises in the same locality
where, it appears, Dr. Edmunds himself formerly practised,
has written the following very able reply to the letter to
which we refer:—

"To the Editor of the 'Times.'

"Sir,—Dr. Edmunds's letter to you in your publication
of this day would indeed be startling if his facts and figures
approached accuracy, but every obstetric practitioner
must see at a glance that such is not the case. I have
been busily engaged in obstetric practice at the east end of
London for several years, and I find, on looking over the
records of 2,000 cases, that the deaths from puerperal fever
and all causes within the month do not average two per
thousand. And why? Not from superior ability on my
part, or even from what is usually called luck, but simply,
I believe, because, taught by the experience I had pre-
viously gained in country practice of the terrible conse-
quences inseparable from the practice of female accouche-
ment and the injury done to Medical men who are called
in to relieve them from the consequences of their mal-
practice, I have always, as a rule, refused to go to cases
where a midwife has been in attendance. Dr. Edmunds
was for some years in extensive midwifery practice in
Brick lane, Spitalfields, and no one knows better than he
that about nine out of ten of the fatal cases occurring in
every Medical man's midwifery practice consist of those
to which he has been called after they have been subjected
to mismanagement at the hands of a midwife or unqualified
practitioner. This will clearly account for the startling
state of the Registrar-General's returns. With regard to
the relative mortality in lying-in institutions, I may state,
as the result of my experience, that no women, however
poor, will avail themselves of these charities unless from
previous good confinements or from the state of their
health they have good reason to anticipate a safe and
speedy delivery; and, on the other hand, whenever they
or their friends have any reason to prognosticate a
dangerous 'time,' they will certainly, at any sacrifice,
secure the attendance of the leading accoucheur of their
neighbourhood. This also points to another cause of low
mortality in lying-in hospitals. In these days of progress,
no Medical man would object to that part of the Profession
relating specially to women being attended by female prac-
titioners, so long as they were properly qualified; still it is
obviously unfair to advocate that practice at the expense of
Medical men, by saying that the cause of puerperal fever,

&c., rests on its being carried to the bedside by the hands of the accoucheur. Dr. Edmunds being Lecturer on Medicine as well as Secretary to the Female Medical College, it is fair to presume that this is a sample of the doctrine inculcated at that establishment; if so, I would advise him before he again lectures to peruse *Ramsbotham*, *Blundell*, or some other of our best authorities on the subject.

"I am, Sir, your obedient servant,
"ROBT. EDWD. SWYER, M.D., &c."

SOCIAL SCIENCE CONGRESS.

THE CATTLE PLAGUE.

Professor Gamgee delivered his views as follows on the vital question of the cattle plague:—There are probably not a few here assembled who will participate in the feeling expressed by the learned chairman of the Public Health Section of this association that the present meeting should not be permitted to disperse without special reference to, and some discussion on, that all-absorbing topic—the Russian cattle plague. This most malignant of all fevers is one of the indigenous maladies of the East. From time to time, during centuries past, it has lurked in the Asiatic and European steppes, killing slowly the rude gray oxen of the Russians, and exterminating the cattle of districts and countries to which it is usually foreign, and to which it might be incidentally introduced. There is some ground for the belief that the pure breed of Eastern plains enjoys some immunity against the disease, and it is the frequent mildness of its attacks in the herds of the Cossack and the Tartar that renders not only possible, but tolerably easy, the conveyance of infected herds from their original homes to parts where their introduction may lead to widespread mortality and famine. Not unfrequently the active agents in the propagation of the plague have been droves of sick oxen dying on the roadside, and otherwise indicating their real and very dangerous condition. Such indeed, was the case during outbreaks noted in history, and which occurred in the 13th, 17th, 18th, and the present centuries. The campaigns of the First Napoleon in central and eastern Europe are memorable for the facilities they afforded, owing to the active movements of prodigious forces engaged in war, for the dissemination of the cattle plague over the greater part of the European continent. With imperfect means of transport, during the presence of large armies in hostile countries it was often necessary to provide thousands of oxen for the transport service, and the supply of animal food for the soldiers. The system of trading and intermingling of stock thus fostered could not fail to afford the best chances for the propagation of contagious disorders; and, all-absorbed with means of offence or defence in relation to each other, the people of various countries had little chance of adopting rational and efficient means whereby to arrest the progress of the *rinderpest*. The battle of Waterloo not only sealed Napoleon's fate, but among the unknown blessings it bestowed on us was protection from this dreaded pestilence. A long period of peace resulted in the promotion of agriculture as of other useful arts. Governments fostered measures which might in ordinary times protect countries from bovine epizootics, and the disease which in 1814 swept away the herds of Germany, Switzerland, and France fell back into its old haunts, and has committed less havoc since. The remarkable outbreaks of 1830, 1841, 1844, 1849, 1857, and 1863, wide in their distribution as they no doubt were, could not be compared to some of the older ones; and instead of following the cannon's roar, they appeared silently on the great roads of commerce, and mostly in a direction from east to south-west, into Egypt or across Turkey and Hungary, as far even as the Pontifical States. The periodic extensions of the malady in the lines of communication established by trade led to our attention being forcibly directed to the subject, as the importation of foreign stock increased in this country. We knew that so soon as any direct communication was established by cattle dealers between Russia and England the murrain of the steppes could not fail to be imported. This opinion was expressed repeatedly, and it was even indicated that the malady would reach us through the Baltic. All that was wanted was that any cargo of cattle direct from Russia should be subjected here to regulations such as those which are in force in Austria and Prussia; but we were freely told that, until the cattle plague came, no one would be convinced of the importance of, or necessity for, such measures. The cattle plague has come; it has reached us through the Baltic, and though we may return the compliment to the Russians if they now want breeding stock, it is evident that ere this the ports should have been closed to direct importations from Russia, even though we were only shutting the door after the steed was stolen. There is much reason for regret that the public press in this country has in too many instances attempted to throw discredit on those who have insisted on the truth that the plague now destroying our cattle is, and only could be, an importation from Russia. As we are compelled to trace plagues in men and animals to their origin if we wish to devise means for their prevention, it is evident that in relation to the present outbreak it was necessary to ascertain all we could as to its cause. To those who have studied the cattle plague in times past—to those who have fathomed the literature of the subject, and not only seen the disease abroad, but mingled with men who have had the greatest amount of experience respecting it—no other view could possibly meet with favour but that which ascribed the malady to direct or indirect importation from Russia. It is certain that to the west of the Czar's dominions the plague never originated spontaneously. That is a truth as much established in the minds of scientific men as the preservative influence of vaccination against small-pox in man or the purely contagious character of the sheep-pox. When I first saw the steppe murrain among the cows of the London sheds, on the 29th of July, I knew that the disease must have been imported. On making inquiries we found that a cargo of Russian cattle and sheep had been brought from Revel to Hull. It was the first cargo that had yet come direct from a Russian port; and fourteen days after a portion of that cargo was first exposed in the Metropolitan Cattle market the strange disease was seen in Copenhagen-fields. This fact alone was startling, and satisfactory enough. The result bore out the predictions that had repeatedly been made, and we proceeded somewhat further to strengthen our belief in the fact that the disease really came through the Baltic. An agricultural society in Esthonia had agreed to supply a certain number of cattle and sheep free on board a steamer at Revel. That society had insuperable difficulties in fulfilling its contract from the scarcity of cattle fit for the London market. The terms of agreement with the London salesmen were that the animals were to be supplied free on board fit for the London trade, but many of the cattle did not come up to the proper standard of weight and fatness. The number supplied was short, and forty-six animals were obtained from St. Petersburg to make up the cargo; but their condition was so bad that only thirteen of them were chosen by the person representing the London importers. Of all the cattle brought to Revel to be shipped to London, three had to be slaughtered diseased by a butcher, a fourth died in the yard before being delivered on board, and an action was brought against the English agent for the price of this animal, which he would not and did not pay. A fifth animal showed signs of illness on the passage, and when the cargo arrived off a Danish port, a letter was sent from the London salesman intimating that "queer things," meaning the cattle, should be taken to Lowestoft instead of London, so as to avoid the doctors. For some reason or other, they were afterwards landed still further from London, at the port of Hull, and there subdivided for sale at different markets. One half left Hull for London at once, and that half propagated the disease. Why the other half did not do so is of no importance to us, as we constantly find, in tracing contagious diseases among men, that, two farmers having bought a herd between them, the one half purchased by one man remains in health, and the other half dies. The cattle sent to London stood the

lon market on the 1st of June, and some of them were exposed again afterwards for sale. They must have communicated the disease to foreign cows near them, for it was these ows which conveyed the malady into the London sheds. On he 24th and 27th of June the plague was already raging in ifferent dairies, and since then it has been widely disseminated. I am perfectly satisfied of the evidence at my disposal n this question, and some of which I need not enter into rther on this occasion; but it may probably be thought at our Government should have caused inquiries to be ade as to the whole history of the cargo from Revel, and ot through consuls, but thorough competent veterinarians nd others who could be trusted to sift the question oroughly. The chance has been allowed to slip, as the sthonians are now not likely to divulge what might injure eir prospects of trade in future, and interested parties ve taken proper precautions to place people on their guard. or me the strong points in the case are—firstly, the preous knowledge of the fact that the disease could only reach through the Baltic; secondly, the fact that the cargo imrted last May were the first direct from Russia; thirdly, e slaughter and death of cattle at Revel, and the sickness an animal on board the ship; fourthly, taking the animals a port distant from London so as to avoid the doctors; thly and lastly, the manifestations of the plague just after e animals had been exposed in the Metropolitan Market. ave thought it proper to enter at length into this statent, as there are many people who have been seriously sled by the fancies and suppositions of those whose knowge of the cattle plague is of the most superficial description. Some may still think we are too positive in our sertions on this point, and there are those who charge us th want of modesty for openly asserting what we believe be the truth in relation to the origin, progress, and prention of the cattle plague. Unfortunately, we well know t veterinary science in this country has been most imperctly taught and studied. We are free to admit that on a t of subjects there is occasion for deep regret that so le has been learnt, and we are conscious of the fact that raordinary efforts are required to raise the status and prove the knowledge of the veterinarian. But we are ed to confess ignorance on the disease now ravaging our rds. We are told "that there is no existing disease reting which Medical men would dogmatize so unhesitagly as the veterinary surgeons have done respecting the le plague;" and we are told "that the doctors are looked to because they have done good work, because they have inished the fatality of our human diseases, and are daily east endeavouring to acquire new victories over nature." , gentlemen, at the risk of being deemed ostentatious, peat that the ignorance has existed on the part of those have done all they could to weaken our influence in eyes of the world. There is scarcely a Medical subject which you would engage to find a hundred of the best that can be had unanimous in their opinion; but have had congresses with nearly 200 of the most ned veterinarians in Europe, where, on the subject the steppe murrain, no difference of opinion could be to exist. It might be positive assertion, it might be matism, that the disease was incurable, that it was also pagated by contagion, and that to diminish its ravages must slaughter the sick and infected; but the verdict the best men in the world, medical and veteri, is unanimous on these points. That verdict is as nimous as any conclusion would be at a meeting of doc- if the subject of human smallpox was broached, and invariable origin of this disease in contagion and its vention by vaccination were discussed. As Professor mann justly observes in his report, just published, if would cure the cattle plague it is doubtful whether we uld venture to do so, considering the danger of thereby ping up many sources of contagion. As to the cura- of the disease, we have had some experience during present outbreak. A small proportion of the animals ected to Medical treatment have recovered. We have ted many, and left many to take their chance. The lt proves that those left to themselves have done as as those that have been treated with all the remedies suggested from the commencement. The chance of cure depends altogether on the severity of the attack, and whenever attempts have been made to follow up a considerable number of cases, and treat them carefully, the result has been a mortality varying from 85 to 95 per cent. It is not astonishing that cures have been advertised and wonderful results announced. The recovery of one or two apparently desperate cases encourages experiments as to treatment, but, so far as our experience has gone, the prosecution of trials has resulted in loss and disappointment. From the commencement of the outbreak, one of my principal objects has been to discover how we might determine before ordinary observers that an animal had the disease. If remedies can be found to prove of service, they must be applied before the changes of structure are so far advanced as to render it impossible to restore health. So far as my observations now extend, I believe that in twenty-four or forty-eight hours before any very obvious signs of ill-health, such as dulness, loss of appetite, &c., are observed, it is possible to indicate that animals are under the influence of the malady. I have no great hopes of success from treatment even at this early stage; but all will admit that it is something to have ascertained how at the earliest possible moment sick cattle may be distinguished from diseased. Before entering on the proposals made for the prevention of the cattle plague, I may be permitted to allude to the contrast offered between veterinarians and doctors, by which it is implied that we have done nothing to acquire new victories over Nature. On former occasions, reference has justly been made to the manner in which, under a proper organisation, no less deadly a disease than glanders in horses has been well nigh banished from our cavalry stables. This has been a victory over Nature, but it has been due to the early slaughter of sick and infected animals. When smallpox ravaged our flocks in 1862, treatment, inoculation, and vaccination were resorted to, until I called the farmers together, and told them how to kill out the disease. In three weeks the malady was stopped. This year the smallpox broke out in Sussex, and, as the disease was no less imported than the steppe murrain, the early slaughter of diseased animals at once extinguished every trace of the pest. Having ascertained that it was the true Russian plague which had reached these islands, we hesitated not to advocate the means found most efficient abroad of preventing contagion and killing the sick. We were at once met by doubts expressed as to the origin of the malady, and assertions stated as to its dependence on conditions of the atmosphere. Government said it lacked powers to control the progress of the malady, and I suggested the formation of a national association for the prevention of cattle diseases. At once steps were taken to diffuse useful information on the disease, and call upon civic authorities, railway and steamboat companies, &c., to aid. Local insurance companies soon came into favour. I attended various country meetings to show the fallacies of local associations, and the justice of my remarks has been amply vindicated by the letter from Sir James Kay Shuttleworth in the 'Times' of the 5th inst. A fortnight back, at Northampton, I spoke of the importance of a Government cattle insurance system. From the commencement I have been opposed to any indemnity from the public purse, and it has been my endeavour to show that, if Government were properly guided in this matter, it could meet the difficulties of the case, and secure control over stock for the effectual suppression of so virulent a malady as the one now raging. It is true that there are other measures to be adopted and gross abuses to be corrected. The one measure not to be advocated is diverting the energies of veterinarians to the cure of the disease. Adopt this course, and there is an end to any proper action whereby the plague may be banished from Great Britain. Turn to the writtten histories of typhus and yellow fever, human small-pox and cholera, and tell us what has been done by curative means. The doctors who have gained victories over nature have gained no victories over these malaadies but by the adoption of preventive measures. Animals can be dealt with differently from men, and a hundred outbreaks of cattle plague might be quoted to prove that to

kill is to save the lives of thousands and tens of thousands. To spare the knife implies propagating and perpetuating the malady.

Mr. Evans, who looked upon the cattle plague very much in the light of a judgment, and Dr. Hall, who concurred in the main with the views expressed by Professor Gamgee, having briefly addressed the section,—

Dr. Rawlinson thought that, without actually throwing their minds back to the days of antiquity, when plague followed the footsteps of great armies, it was quite intelligible how, in barbarous countries, cattle being shipped for considerable distances across stormy seas, might in the absence of suitable precautions engender fatal diseases. To come nearer home, our farmers displayed far too great a disregard of sanitary arrangements, with regard to their cattle. They never thought of giving them fresh, clean beds, and hence when disease was fostered, the only remedy was said to be the knife. This he did not believe, for in one case where a friend's bullock, said to have the cattle disease, was driven under a shed, he insisted that if it were left there in the dirt the beast must die; and the shed having been properly cleaned and ventilated the animal recovered.

Dr. Wilson was disposed to attribute the spread of the disease entirely to atmospheric influences.

Mr. P. Holland regarded the cattle disease as a form of typhus of a very rabid kind. He did not look upon killing as the only remedy, but said it was often cheaper in the case of horses, to kill a lame animal than to attempt to cure him.

Dr. Lankester regarded the evidence in support of the importation of disease from abroad as impeachable, maintaining that, if it were in the power of dirt or filth at home to generate disease in cattle, they could never have escaped till now. There certainly had been no such predisposing cause in the case of Lord Granville's establishment, where, in cowhouses perfect in every respect, 120 out of 140 animals had died. It remained a mystery for some time how the disease could have gained admission there, but at last it was accounted for by the supposition that children who were very fond of going to look at these animals must have carried the infection from a number of Dutch cows placed in an adjoining meadow, near to which ran the ordinary footpath.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Professor BOECK, of Christiania, contributes a paper "On Syphilisation," in which he states that the results are very much modified if mercury has been previously given. He asserts that syphilisation produces the most salutary effects when no other treatment has been previously tried. But out of seventy-two patients in the hospital who had been treated by syphilisation, twenty-two returned with relapses, or thirty and a-half per cent. Syphilisation may be successfully employed in the early constitutional (or secondary) cases and in the late constitutional (or tertiary) cases, but Professor Boeck states that in both cases he has given the iodide of potassium in addition, but he denies that the good effect is due to this salt. He argues that the early adoption of syphilisation will often prevent some of the worst constitutional results of syphilis, as may be proved by comparing cases which have been treated by syphilisation without mercury, with cases treated only or chiefly by mercury. But Dr. Boeck admits that after syphilisation has been performed with apparent success, many relapses occur.——Dr. EDWARD SMITH contributes a paper "On Alcohol," in answer to some remarks made in favour of the views promulgated by the late Dr. Todd, which are much extolled by his pupils, but which, Dr. Smith conceives, are not adopted by the Profession at large. Dr. Smith discusses at some length the question which has been lately so much debated, namely, whether alcohol is eliminated unchanged from the body, or undergoes transformation in the system, and he leans to the theory of elimination, but still he considers it to be a powerful and valuable medicinal agent.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. HANDFIELD JONES continues his Lumleian Lectures "On some Points in the Pathology of Nervous Diseases." The present lecture is occupied with the description of the kind of paresis of nervous tissue which appears to be induced by impressions conveyed to the centres through afferent nerves. This kind of paresis is observed in the case of the heart and the intestines, and it may be modified by external stimuli such as galvanism.——Dr. GEORGE HARLEY continues his lectures "On the Urine and Diseases of the Urinary Organs." The subject of the present lecture is "Diabetes," and Dr. Harley describes the different circumstances, both of a mental and physical character, which may give rise to the appearance of sugar in the urine. Dr. Harley divides the forms of diabetes into two groups, one arising *from excessive formation* and the other from *defective assimilation* (mal-nutrition). He then considers nerve-lesion and nerve-disease as a cause of this, and he shows that sugar may be developed artificially in the urine by irritating some portion of the nervous system, as has been done by Bernard and others. He also adduces a case in which a man became diabetic on receiving an injury to the head, but as he recovered, the sugar in the urine gradually disappeared.——Dr. JOHN CHAPMAN communicates a paper "On the Cholera at Southampton, and its Successful Treatment by Cold and Heat along the Spine." The cases are seven in number, and the results are believed by Dr. Chapman to justify the anticipations he had formed as to the value of his treatment. He even states that patients in the state of complete collapse from cholera may now be restored with astonishing rapidity; while the subsequent congestions and fevers may be controlled to a great extent. Dr. Chapman records the details of the cases and draws the following practical conclusions:—

"My week's experience at Southampton leads me to the following suggestions to physicians about to treat cholera patients by modifying the temperature along the spine:—1. To apply ice along the whole spine while algide symptoms are overcome. 2. As soon as these are overcome, to restrict the ice to the lower half of the spine, and to apply it there continuously until the vomiting and purging begin to subside. 3. Then, after each bag of ice has melted, to allow intervals—increasing in length as these symptoms decrease—before applying the next bag, and gradually to shorten the time of each application. To avert any threatened cerebral or pulmonary congestion by means of the double-columned water-bag 5. And if there be insomnia, to induce sleep also, by means of ice. The last observation I have space for here is, perhaps, the most important of all. Algide symptoms are produced not merely by congestion of the sympathetic nervous centres, but by congestion of the lungs, which prevents the due circulation and oxygenation of the blood. The pres-

lgide symptoms is not alone, therefore, a sure indication f the necessity of applying ice along the spine ; for if ıose symptoms proceed from pulmonary congestion, ice ill increase them, whereas heat between the scapulæ will eedily restore heat to the whole body. The danger of istaking the cause, and therefore the remedy, of coldness the surface, is greater in cases of cholera when the dis- se has advanced to its second stage."

Mr. LLEWELLYN POWELL describes the "Post-Mortem xamination Eighteen Hours after Death," of a man who ed from the effects of lightning.

"CYCLOPS'" TWENTY-THIRD LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—That hundreds of men should have observed in ery generation for as many years the peculiar constipated bit of some families and individuals, and never treated it as ything but an irregular and morbid condition, to be rrected and brought into one more consonant to general lief, is something startling ; that in many of the ills and cidents to which the human frame is liable, the first thing ıture does is to cause constipation, and so conserve e elements of the colon. That these facts have never en sifted or inquired into seem to show an utter unbelief ıt any benefit can accrue therefrom, or indeed, quite the erse, and that Nature was wrong, and consequently ıorant of her own operations. Certain it is that the nservatism of constipation was never considered in the ht of a Vis Medicatrix Naturæ. It is quite a new ctrine to say that all this time this very act of hers was e of her prime movements of health. For instance, oughout the whole class of milliners' girls, a constipated bit prevails ; some of these young women eat only getables or bread and butter, some only meat, and in some only like it well done and even burnt up ; while ers of more cadaverous complexions like it underdone l almost raw. They are, as a class, most capricious in their ding ; their bowels are only open about once a week or ı days, some a fortnight or more, yet they go on pretty gularly in their duties. If they take aperients, they are ays worse for them, and if they can afford to go to a tor, and have the eternal blue pill for their liver, and harties for their bowels, they soon begin to waste and drop easy stages into consumption. It is the most fortunate ıg in the world for them that they cannot afford to pay dical bills or fees. Yet they have their own sense in this, and will tell you they are never better than when r bowels are confined, and always that they are worse r aperients. In fact, their bodily health rests on their ıg poor in pocket and conservative in their bowels. In ıtenant Bligh's narrative of the mutiny of the 'Bounty,' n he and seventeen others were cast adrift in an open boat, nentions that for above a fortnight and three weeks the le crew were constipated, and that they did not appear any worse for it. Certainly not! it saved them ; but if there been a doctor on board with any aperients, he would doubt have given them all round, and not one would been saved. Yet physiology never took up this subject ever learnt anything by it. A gentleman told me that on a ride across the Andes, which lasted above a ight, his bowels were not opened at all. He often dered at it, but I explained to him the reason, and he felt that this natural law saved his life, and no doubt l. In the incubation of birds, this fact obtains to a t extent, and the great heat that is engendered from bodies serves the end in view; but a common hen ıg with loose bowels will bring no eggs forward. ng insufficient heat for the purpose, her labour is all In the hybernating animals, a two, three, or four hs' constipation is a regular thing. This is well n to the bear-hunters, and if the she bear loses her , even the parting of a few scybalæ, she loses her ic and strength, and she fails in the maternal end she n view. I could bring forward many facts of the same kind to show the benefit of the conservatism of constipation in the healthy and normal state, but these are sufficient for the present. In the opposite states, such as in fevers, the very first thing Nature does is to lock up the bowels. In severe falls, where the body gets shaken to its very centres, she does the same. In many diseases also, besides fevers, she acts in the same manner. Even in diseases and certain affections which man himself produces in the human system to relieve others, such as, in many surgical operations which more or less affect the whole condition of the system and its secretions, the first thing Nature does is to conserve the fæces. Notwithstanding all these glaring facts, neither physicians nor surgeons will allow it. A fixed prejudice on this matter still holds on to every man, however high his position in the Profession. A friend of mine, to whom I am much indebted for his physiological researches on these points, went some few years ago to Mr. Baker Brown's *Home* to witness some of his beautiful operations for recto- and vesico-vaginal fistulæ. An operation was performed on that day on a young governess for fibrous enlargement of the womb, and which was removed, and weighed about twenty pounds. He said he could not help telling Mr. Brown, when all was over, that he would lose his case, and he did. Mr. Brown, of course, hoped not. But he told him he would, because he did not understand the physiology of the colon. Mr. Brown thought this very hard upon him, but my friend asked him how long he intended to keep the bowels confined; his reply was, "for three or four days, perhaps." My friend answered, "Why not make it weeks?" Now, Mr Baker Brown did not turn upon his heel, or think my friend somewhat insane, but asked him his reason; for, as he justly observed, "you do not tell me this without one." My friend did so, and went several times afterwards to the *Home*, and Mr. Brown followed his plan. The sequel was, that in the latter part of the year 1862, that of the Great Exhibition, Mr. Baker Brown called upon him, and said he had had many foreign Professors that year to see his operations. But he emphatically said, 'My operations have not surprised them half so much as my Medical treatment, and they were all astonished at my conservancy of the patient's bowels for any time I wished." The consequence of his pursuing this practice has naturally reduced the death-rate after these Cæsarean operations; fewer die and more are saved.

Now although surgery now-a-days leaves nothing to be desired, the successful issue of operations often depends upon the after Medical treatment; and this Mr. Brown fully admitted, and gave my friend all the credit. If this was done oftener in our schools, even as an *empiricism*, the success surgeons would meet with would surprise them. I have had my friend's permission to record these circumstances, as I wish myself to take the question out of the region of empiricism, and place all these wonderful laws on a scientific basis, on which alone it can firmly stand. It is therefore incumbent on the physiologist to find out why this fact is beneficial in many idiosyncrasies in health, and why it often checks disease and gradually assists the secretions towards a condition of health. What then, may we ask, is the reason of the natural constipation of those who have this state in health? Why is it that in given conditions in the system from persons being placed in some greatly altered circumstances that constipation becomes a beneficial action, when the reverse always occurred before? Why also in disease should this fact come to their immediate assistance and become a Vis Medicatrix Naturæ if man would only let it alone? Why, under many circumstances of violence done to his system, is it that this fact is a sequitur? Even in the health of other individuals with the greatest regularity of the actions of the bowels, we have to ask how much of this depends upon the colon? In short, we have to learn as much philosophy from what may be called the opposite conditions of the colon as we have of its regular actions and the organ itself. We have to ask ourselves how much the philosophy of life depends upon the physiology of the colon, and the usefulness of its contents, and come at once to this point:—Are the fæces useful to life as fæces? Has Nature been right or wrong in

making the receptable such an one as she has done for them? If she is right, then I say the whole practice of physicking and purging to the extent that it has been carried and even carried on now, is an ignorant delusion of man, who has had no justifiable right to use as his motto :—"Opiferque per orbem dicor," with Apollo as the mythological God of Medicine as his crest. He has had no right to use any such godship or any such motto, when he has continually done the reverse of good by opposing natural laws, and made disease where he should have stopped its first inroads, and by playing (all unconsciously I will admit) into the adversaries' hands; and has, as a matter of course, left death to reap the harvest. To ignorance of many of the great laws of Nature are all these things to be laid. Many who have been only wise in their generation, and many even living now, have expressed their unbelief in the "Ars Medicinæ," because disappointed at every turn in their apparently wisest axioms and modes and means of cure, have said: "Better had it been for the world if neither physician, surgeon, leech, nor even midwife had ever existed." Thus because they quarrelled with their own ignorance they seemed to infer that nobody could ever know more than they did, and so condemned the God-like calling itself. This is always the case. But at the risk of shocking society with new ideas, I am bound in honour to myself and duty to my fraternity to express my views on these important points, and show that it is to the colon and its filthy and disgusting contents that we owe much of the health and happiness of our lives, and not only this, but through an inscrutable wisdom, the advance of science and knowledge of matter.

I am, &c.,
CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

THE CHOLERA IN FRANCE.

Towards the close of last week there was a report, which soon gained ground, that the Asiatic scourge had entered Paris, and had, in fact, been there for several days. It was reported that from the 22nd of September to the 1st of October there had been forty cases of the disease, with twelve deaths. Twenty of these cases were inhabitants of Montmartre and Batignolles. They were all removed into hospital. In addition, twenty-seven cases were reported in private dwellings. In order to prevent alarm, the 'Mémorial Diplomatique' published a note putting the public on their guard against exaggerated reports on the subject of the cholera in Paris. It admitted that the malady does certainly exist in the capital, but simply in isolated cases, and having in no wise the epidemical character which marked the two previous invasions of the scourge. "There are," it states, "at most twenty cases of cholera per day in the hospital—a number without importance, especially in the present season, when the use of fruit, vegetables, and crudities, with the drought, is sufficient every year to give rise to a certain amount of sporadic cholera. Notwithstanding the above-mentioned causes, statistics show that the mortality has of late been less considerable than in the corresponding period of last year." The 'Gazette de France' states that it is on the southern side of Montmartre and of the Batignolles that the cases have principally arisen, and adds :—"Both these districts are, unfortunately, exceedingly dirty, as well in the interior of the houses as in the streets. Cleansing of an extensive character is required, and in that respect the inhabitants have as much to do as the Prefect of the Seine."

On Saturday and Sunday a considerable number of cases of the malady—over sixty—were reported in the city, and on Friday the 5th, there were not less than twenty deaths. It seems that the disease was brought into Montmartre from Marseilles by a person suffering from it, who died in Montmartre. On Monday, the 9th, the disease was considered to be on the decline. The places in which it was most rife were in the northern division of the city.

That the epidemic in its true Asiatic type does exist in Paris is proved, we fear, by the steps taken by the Government. For some days past the authorities have been saturating all the foul places with solution of chloride of lime. This was of some significance, but the most important fact is that on Tuesday last a "service Médical" was formally organised under Ministerial direction. Twenty-two soldiers of the Imperial Guard are reported as being under treatment for cholera at the Military Hospital of the "Gros-Caillon."

PARISIAN MEDICAL NEWS.

APPLICATION OF CAUSTICS IN PHLEGMONOUS ERYSIPELAS.

Cauterisation being more generally employed formerly than at present, has doubtlessly been resorted to in cellulo-cutaneous erysipelas; but it appears probable that it never has been instituted in the manner adopted by a Surgeon-in-Chief of the Navy, M. Long, in the cases forwarded by M. Pasqualini, Interne of the Hôtel Dieu of Toulon, to the 'Gazette Hebdomadaire.'

The first patient was a brewer, aged twenty-eight, who had been ailing for three days, and whose condition when he was admitted into the hospital on 18th July, 1864, was the following :—

The right arm was in its entire extent swelled, painful, of a dusky red, and covered with livid vesications; the redness and tumefaction extended from the fingers to the axilla, the margin of the discoloration being indistinct; the axillary glands were enlarged, and œdema was present in the internal and inferior parts of the arm, and also behind the elbow; a large bulla, four inches by two, existed on the anterior region of the arm. Deep-seated fluctuation was present, with fever, agitation, dilatation of the pupils, wandering, and a soft, regular, and rather frequent pulse (80). Beef-tea was prescribed, and a 4 oz. mixture containing two drachms of acetate of ammonia. Vienna paste was applied over thirty spots about half an inch in diameter, in four longitudinal rows, and the limb wrapped in cotton, was laid on cushions forming an inclined plane of which the hand occupied the apex.

On the 19th the patient was much worse; the delirium was more violent in the night, the tongue was black and dry, and the pulse quicker (85). Fifty other rounds of the escharotic were applied over the whole surface of the arm, and beef-tea was prescribed.

On the 20th the delirium and fever ceased altogether, the limb was less swelled, and the tongue less foul. On the 22nd, suppuration set in in the cauterised spots, and the arm was much reduced in size. The patient was also enabled to move the limb slightly, and his general condition being satisfactory, soup was allowed. On the 24th suppuration of the issues was fully established, appetite was restored, and solid food was prescribed. On the 25th the skin was found extensively detached at the back of the arm and in the region occupied by the large vesicle we have described, and the suppuration was copious. Flakes of mortified cellular tissue four inches in length were removed behind the elbow, where the skin was also detached. On the 30th, marked improvement was observed in the condition of the arm, the suppurative action appeared to have ceased, the skin again adhered to the subjacent parts, and the wound on the inside of the arm was covered with healthy granulations; no sloughing of the integument was noticeable in any part. The patient was now enabled to use his arm, and its movements were restored. The granulations were touched with lunar caustic, and on the 3rd August the man was discharged from hospital.

In the second case, in which the number of cauterisations was reduced by one-half, the suppuration was more copious and the detachment of the skin more extensive.

Dr. Carence, who preceded M. Pasqualini as interne of M. Long's ward, also records the two followidg cases :—

Mary R—, aged fifty, admitted into the Hôtel Dieu on the 3rd of January, 1864, was affected with phlegmon involving the whole of the leg and the two lower thirds of the thigh. The swelling was considerable, and deep-seated fluctuation was present; the integument was covered with vesications, and her general condition was most alarming, and aggravated by intense delirium. One hundred and

hirty applications of Vienna paste were made along the mb; the general symptoms promptly improved, and the norbid secretion escaped through the apertures made by ne escharotic. After an interval of three months a com-lete cure was effected.

L., a labouring man. Deep and narrow wound of the bow, followed by tumefaction of the arm, from the axilla the wrist; phlyctenæ on the surface, fever and delirium. venty cauterisations were performed, and the patient mained ten weeks in hospital. When he was discharged, ght stiffness remained in the joints, but he was visited by . Carence a month later, and at this period no difference is perceptible in the movements of the two arms.

M. Long has invariably followed this system with all t constant success. His object in applying the caustic to arrest the mischief, prevent detachment of the skin, d give issue to the pus.

Sixty or eighty cauterisations applied over a limb, in the rlier stage of the disease, produce powerful counter-irrita-n. In most instances the general condition of the patient es its alarming aspect in the course of twenty-four hours, e tumefaction diminishes, and the suppuration becomes nited. Likewise, in cases of gangrene, M. Long often plies the same remedy on the margin of the healthy rts. The bright red line of demarcation always forms re, the further progress of mortification is checked, and e necessity for amputation removed, or the tedious and ngerous process of suppuration averted. The efficacy of terisation for the purpose of obviating detachment of e skin is apparent in the fifth case adduced by M. Pasqua-i.

B., aged thirty-four, after a severe fall on his head, was mitted into hospital. The scalp was entirely torn off m one side of the head, from the fronto-parietal suture the occipital protuberance, and was inverted over the ek. The parts were gently cleansed, and the flap res-ed to its place, where it was secured by two sutures. the following day the flap was found in a turgid state, tended by subjacent sero-sanious fluid, and nearly ached. The hair was shaved off, and four rounds of nna paste were applied. In the course of two days the puration was arrested, the flap adhered firmly, and in a ek the man was discharged.

n conclusion, M. Long's method is deserving of serious ntion, especially as only two out of sixty cases thus ted terminated fatally, and as he has never been under necessity of performing amputation. The application he Vienna paste is moderately painful, but leaves in-ble scars, an unimportant disadvantage, remarks M. ualini, if the formidable nature of the disease be con-red.

Accidents Caused by Lightning.

appears that in France, between the years 1835 and , the number of persons instantaneously killed by ning was 2,342, nearly 5,000 having also suffered more ess severe wounds inflicted by this cause. Where ning falls on groups of persons of the two sexes, men nore generally injured. The author does not inquire the cause of the greater affinity of atmospheric electri-for the male sex, but he remarks that, even amongst some individuals are, from the nature of their con-tion, more liable under equal circumstances, to expe-e the effects of lightning. Arago remarks that some ns have the property of interrupting the electric nt even when they occupy the second place in the . These individuals are exceptionally non-conductors, must, therefore, be classed amongst the non-conduct-odies which lightning seldom strikes. These marked ences, of course, imply shades, and each degree of actibility corresponds during a storm to a varying e of danger. If a human subject possesses a conduct-ower as great as metal, he will be struck as frequently tal; and an individual who has the faculty of arrest-current has not much more to fear than if he was of glass or of resin. Between these extremes persons e found who attract lightning only in the same degree one, wood, &c. In the phenomena caused by atmos-pheric electricity, the situation occupied by the individual is not therefore the sole consideration, but his physical constitution must further be taken into account. A host of cases might also be adduced to prove that man, in this respect, is far less liable to injury from lightning than animals.

It is a very prevalent opinion that during a storm trees afford but a very unsafe refuge. M. Boudin seems to share in this popular view, and yet his statistics present us with this contradictory result—that, in a number of 141 persons struck by lightning *in the open fields*, 36 only had sought the protection of trees. As to the nature of the latter it should be noted that beech trees have occasionally been struck, a fact which shows that Maxwell and the last Scientific Congress at Manchester were incorrect in their statement of the immunity enjoyed by this tree.

Another very singular circumstance, adverted to by M. Boudin, is the electric power preserved by the body of persons recently struck by lightning, and he adduces two cases which fully illustrate the fact. The first concerns a man who, on the 30th of June, 1854, was killed by lightning in the neighbourhood of the Garden of Plants in Paris, and whose body remained for some time exposed to a heavy fall of rain. After the storm, two soldiers, who attempted to remove the corpse, experienced each a severe shock. In the second case, two artillerymen were ordered to raise two posts of the electric telegraph, demolished by lightning on the 8th of September, 1858, at Zara, in Dalmatia; they experienced at first slight shocks, but were afterwards suddenly struck to the ground; the hands of both were severely burnt, and one of the men, for a time, gave no signs of life. His comrade, while attempting to rise, immediately fell back again, when his elbow came in contact with the body of a person who had hastened to his assistance. This individual was also struck down, experienced various nervous symptoms, and a burn was observed in the spot touched by the elbow of the injured man.

Thoracentesis.

Thoracentesis is at present a general subject of discussion, both within and beoynd the walls of the Academy of Medicine. Our readers will therefore not be suaprised to find in the present number several communications on this question, which does not appear likely to derive much light from the debates still going on at the Academy. It is obvious that, although opinions may differ as to the amount of danger involved by the ingress of air into the pleura, all practitioners agree that the contingency should be avoided; and it is also evident that Reybard's procedure, amended by Mr. Barth, affords every security, and is applicable by all surgeons. The operation cannot, however, be regarded as altogether innocuous. Instances are on record of fatal syncope supervening immediately after its performance; the point of the trochar has occasionally been driven into the lung, and the instrument has been sometimes also pushed through the diaphragm into the peritoneum. We need not allude to cases in which the puncture has been improperly resorted to, when no effusion was present, because, as will be seen in a case by M. Lucas-Championnière, the mistake may be easily avoided by careful previous auscultation; but if it is right not to exaggerate the perils of thoracentesis, and, on the contrary, to point out its many advantages, it is at the same time necessary that practitioners should be fully aware of its possible consequences, in order not to have recourse too hastily to the procedure, and not before acute inflammatory action has been subdued by depletion, digitalis, nitrate of potash, and counter-irritation.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 5th:—Henry Melville Brewer, Newport, Monmouthshire; Richard Phibbs Irwin, St. Peters road, Mile end; Robert Jolly, Albany street, Edinburgh; Charles John Myers, Talbot Villas, Tottenham; John Norrish, Tavistock street, Plymouth; Henry Cripps Rogers, Newport Pagnell, Bucks.

The following gentleman also on the same day passed his first examination :—Thomas Edward Bowkett, London Hospital.

Of the 128 candidates who presented themselves for the Preliminary Examination in Arts on the 29th and 30th ultimo, the following passed, and received certificates of proficiency in general education :—J. K. Andrews, A. H. W. Ayling, W. C. Barnish, F. W. Barron, A. H. Barron, W. Berry, R. Brockelsby, T. Browne, J. P. Brumwell, J. L. Bullock, H. Button, J. A. Campbell, A. G. Cawood, H. Choldicott, J. L. Chambers, C. Clapham, W. Claridge, J. R. Clourting, Ellen Colborne, E. O. Copland, D. Davies, T. Dawson, H. J. Dax, T. Docking, W. T. Drew, L. Duke, A. R. Dunnage, S. V. Durrand, E. Elphick, G. England, E. F. Gaitskill, J. C. Gibson, A. Gillingham, H. Goude, F. Greenwood, E. J. Hale, A. L. Harrington, A. Hogg, R. B. Hogg, S. L. Jackson, M. T. Kavanagh, A. Kershaw, C. H. Lawrence, J. T. Leigh, David Lloyd, R. H. Lloyd, W. H. Lloyd, J. Maffey, L. W. Marshall, J. B. Maskew, R. Mason, A. Mitchell, W. M. Noott, C. J. Oldham, J. B. O'Connor, A. H. Parker, J. Phillips, E. J. Plummer, W. J. R. Ray. F. H. de Rheims, W. K. Rix, J. J. Robinson, W. Roche, J. Rouch, C. E. Rowling, H. Salt, A. Sangster, J. Scott, M. F. Simon, H. Skelton, H. C. Smith, W. W. Smith, R. Stephens, W. B. Taylor, G. D. P. Thomas, L. M. Thomas, G. F. E. Towt, J. Tuck, E. P. Vines, J. F. Vizard, W. Wearne, A. J. Whitefoord, G. Whittaker, W. H. W. Wilkinson, G. Willis, J. B. Wilson.—W. Claridge, E. O. Copland, H. Goude, Henry Salt, M. F. Simon, L. M. Thomas, and W. H. W. Wilkinson, received special certificates of honour.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The following is a list of candidates who passed the Examination on October 11th as Pharmaceutical Chemists :—John Angior, Liverpool; John Averill, Stafford; James Best, London; John Bienvenu, Southampton; Henry Jones, Llanfachraith; W. H. Lenton, East Dereham; Thomas Stokoe London; Cornelius Williams, Pembroke Dock.

THE SURGEONCY OF THE SURREY COUNTY GAOL.—Mr. Rendle has publicly announced his intention of withdrawing from the competition for this office, on the ground, as he states, that "the election appears to be already predetermined." Surely there must be some misapprehension on the part of Mr. Rendle. If not, the magistrates are bound to give some explanation of the charge brought against them.

SOCIETY OF APOTHECARIES.—At the recent examination for prizes in Botany, annually given by this body, the successful candidates were—Stephen Wooton Bushel, Guy's Hospital, a gold medal; Henry Franklin Parsons, St. Mary's Hospital, a silver medal and book.

DEFICIENT VACCINATION.—In the quarter ending June 30th, there were 259 births registered in Exeter, and only nineteen cases of vaccination.

POISON IN THE SEWERS.—Dr. Letheby has analysed the sewage taken from the main sewer in Blackman street, Borough, where three men engaged in flushing the sewer lost their lives on the 14th ult. Dr. Letheby, in his report to the Metropolitan Board of Works, says the sample was giving off abundance of sulphuretted hydrogen and carbonic acid. The composition of it was the same as that taken from a sewer in Beech lane, Barbican, into which the refuse from one of the establishments of the Aërated Bread Company was discharged. The Aërated Bread Company are in the habit of employing a mixture of whiting and oil of vitriol for the generation of carbonic acid, used in the vesiculation of the bread, and when this mixture ceased to evolve the gas in sufficient quantity for their purpose, it is discharged into the sewer, where it continues to give off carbonic acid in such volume as to render the atmosphere unwholesome. About half a ton of this refuse has been let into the sewer at a time, and Dr. Letheby has reason to believe that it not only evolves carbonic acid, but it also, from its acid nature, causes the escape of sulphuretted hydrogen from the sewer mud. Experiment has proved that air with less than 10 per cent. of carbonic acid, or with only from 1 to 2 per cent. of sulphuretted hydrogen, may be immediately fatal to animal life. Mr. Bazalgette has therefore recommended the board to order the bread companies to desist from discharging their manufactured refuse into the sewers. The board adopted the report.

PERSONS BITTEN BY DOGS.—A Parliamentary return has just been issued of all persons bitten by dogs and conveyed to hospitals between the 1st of January and the 28th of June last. The numbers are as follows :—Charing-cross, 55; German Hospital, 9; Guy's 40; London, 70; Middlesex, 32; Royal Free, 13; St. Bartholomew's, 61; St. George's, 28; St. Thomas's, 27; Westminster, 24; and Seamen's Hospital, 1. One death from hydrophobia took place at Guy's. At St. Thomas's a man died from hydrophobia caused by his dog licking his face.

THE PUBLIC HEALTH.—In the week that ended on Saturday, Oct. 7, the births registered in London and ten other large towns of the United Kingdom were 3,883; the deaths registered 2,640. The annual rate of mortality in the week in those eleven towns was 24 per 1,000 persons living. In London the births of 1,042 boys and 1,016 girls, in all 2,058 children, were registered in the week. In the corresponding weeks of ten years, 1855-64, the average number, corrected for increase of population, was 1,852. The deaths registered in London during the week were 1,193. It was the fortieth week of the year, and the average number for that week is, with a correction for increase of population, 1,209. The deaths returned are slightly below the estimated number. Eighty-three deaths occurred from diarrhœa.

PRECAUTIONS AGAINST CHOLERA IN FRANCE.—The head physician of the Paris and Strasburg Railway Company has posted special instructions in all the stations on that line as to the precautions to be adopted in case of an attack of diarrhœa. The company has, moreover, distributed among their *employés* boxes containing the medicine required at the first appearance of cholera, so that travellers and employés may find such remedies close at hand as are frequently sufficient to arrest the progress of the disease.

THE SOCIAL SCIENCE CONGRESS.—On Monday week there was a large attendance of members of the Congress at the Music Hall, Scorey street, Sheffield, to hear an address from Dr. Lankester, President of the Health Department. Dr. Lankester alluded to the ravages of cholera and of the cattle plague, and said he would not attempt to settle the question of whether these diseases were contagious or not. There were two great schools, one of which held that zymotic diseases were produced by special poisons. These were called contagionists. The other school did not believe in the existence of these special poisons, but believed that sanitary neglect and dirt sufficed to produce zymotic diseases. These were called anti-contagionists. He believed that the extreme views of each school were wrong, and that the sanitary measures directed by either party in the present state of knowledge of diseases would plunge us into worse evils than quiet submission to their unresisted influence. Whilst all agreed that small-pox was contagious, and that bronchitis was not, there was a large class of diseases on which high authorities differed, and it was of great importance to pursue an inquiry into the origin and nature of these zymotic or pulmonary diseases, which annually carry off 100,000 of our population. For this purpose three circumstances demanded attention. First, the poison supposed to kindle the disease; second, the medium that conveys it; and third, the personal predisposition to take the disease. As to poisons, even the anti-contagionists admitted that conglomerations of filth and continued exposure to unhealthy exhalations predispose persons to take in the disease of special poisons, but there is no evidence that these agents, though capable of destroying life, are capable of producing alone any of the particular forms of miasmatic disease. The same doctrine applies to diseases amongst cattle. The learned doctor, after some further observations on the causes and development of disease, proceeded to say that in the removal of sanitary impediments our Legislature wanted earnestness. All our Acts of Parliament were so framed that they could be defied with impunity. The great bar to sanitary action in our vestries and local boards is their parsimony; and if they could be once made to see that disease and death are the most costly luxuries in which man can indulge, they would possibly

e more scope to the action of their Medical officers of lth. Perhaps one of the greatest improvements that ld take place in the London system would be the ointment of the Medical officers of health for life, and ucing their numbers, giving them larger districts to erintend, and appending salaries which would render it ecessary that they should attend to private practice.

AMBRIDGE.—By graces of the Senate, passed at a con-gation 12th Oct., the following appointments were made: r. C. J. Hare, Caius College; Dr. G. M. Humphry, ming College; Dr. P. W. Latham, Downing College; e Examiners for the First M.B. Examinations, and for First M.C. Examinations. Dr. Paget, Caius College, e Examiner for second M.B. Examinations. Dr. Hum-, Downing College, T. Holmes, M.A., to be Examiners he Second M.C. Examinations for the ensuing year.

OSPITAL FOR CONSUMPTION, &c., BROMPTON.—The plain-General to Her Majesty's Forces (the Venerable . Gleig), on Sunday last preached at All Saints' Church, er Norwood, in behalf of the funds of the Hospital for sumption and Diseases of the Chest, Brompton. At the of a very impressive and appropriate discourse, the cher said that the value of the institution for which he to plead could not possibly be over-estimated; in fact, was none for which a stronger appeal could be made for this hospital. The hospital accommodated 210 in-nts, and between 7,000 and 8,000 new cases were pre-ed for last year among the out-patients. The expenses necessarily heavy, and there was a serious increase in rice of provisions, especially meat and milk. To give gle instance, 300*l.* would be added to the outlay in con-ence of the rise in the price of milk. Besides all that lone at Brompton, the preacher said it was intended, in pinion wisely, to establish a depôt, so to speak, in the d of Madeira, to which twenty patients would be sent e winter. He trusted that these, and perhaps in the e a thousand others, would there be restored to the ealth which was to all, but more especially to the work-lasses, a priceless blessing. The collection at the close e sermon amounted to 93*l.* 15s. 8d., which included a l contribution in aid of the Madeira Fund.

EATMENT OF THE CATTLE DISEASE.—Mr. Frank land suggests, in the columns of the 'Times,' that the sed cattle should be treated in the same way as the lions, , and leopards were in the Zoological Gardens in 1851, those *carnivora* were seized with a similar disease. Mr. land says:—"The animals attacked by this disease the epidemic of 1851 were four lions, three lionesses, gers, two cheetahs, and four leopards; of these, one d one lioness died on the 20th of August, before the te of potash (the treatment referred to) was commenced. single death occured after its exhibition, although the ls all suffered from the disease with strongly marked oms. Since this date, Mr. Bartlett, superintendent of ological Gardens, has found the chlorate of potash ent to be most beneficial to the animals under his , be they antelopes, deer, *carnivora*, or other deni-f the garden. In order to show the little danger of ans employed, it must be mentioned that, on the 26th ust, 1851, three lions drank six quarts of water, in had been dissolved 480 grains of chlorate of potash. s this, they each had 20 grains in the food, making a f 540 grains between three lions in one day. The dose for an adult ox or cow would commence with ounce given morning and evening. On the fol-day, if the symptoms do not diminish, the dose might bled, increasing it on the third day to half an ounce; any circumstances, discontinue it on the fourth day, ve the system a day's rest, and then give smaller doses ill the animal is convalescent. The best mode of ad-ering it is as follows:—Dissolve half an ounce of te of potash in one quart of boiling water; add to this arts of cold water. The animal, being thirsty from ease, will drink then three quarts, and then give him l quantity of water; he will drink the water containing dicine if allowed to become thirsty, and voluntary g is far better than any drenching.

DEATH.

KING.—On the 10th inst., at the residence of her son-in-law, Dr. G. de Gorrequer Griffith, 9 Lupus street, S.W., Hannah King, widow of the late Henry King, Esq., M.D., Surgeon H.M. 33rd Regiment, and of Elderslie, Dublin.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, OCT. 18.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, OCT. 19.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Harveian Society, First Meeting of the Session 1865-66.—Professor Boeck, of Christiania, "Remarks on Syphilisation;" Dr. W. Camps, "Further Remarks on Epilepsy: the Majuscular Variety."

FRIDAY, OCT. 20.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, OCT. 21.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

MONDAY, OCT. 23.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metropolitan Free Hospital, 2 p.m.

TUESDAY, OCT. 24.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Principles and Practice of Medical Jurisprudence. By A. S. Taylor, M.D., &c. London: John Churchill and Sons.

On Some of the Causes and Effects of Valvular Disease of the Heart. By T. R. Peacock, M.D., &c. London: John Churchill and Sons.

On the Nature and Treatment of the Cattle Plague. By R. H. Allnatt, M.D. London: John Churchill and Sons.

Ligature of the Left Iliac Artery, being the Second Operation in Ireland, and the First Successful Case of it. By William Hargrave, A.M., M.B., &c. Dublin: Thomas Deey.

Elements of Social Science. By a Graduate of Medicine. Sixth Edition. London: E. Truelove, 240 Strand, W.C.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

DR. H. R. informs us that a patient who had been under homœopathic treatment informed him that the homœopath recommended the patient not to take any medicine to open the bowels *except* castor-oil; and our correspondent asks whether castor-oil is a homœopathic remedy, and whether, on the principle *similia similibus*, &c., it has ever been known to cause constipation.

MR. J. T. R.—We cannot at present offer any decided opinion as to the merits of syphilisation as a remedy for venereal complaints. We understand that Professor Boeck will introduce the subject at the approaching meeting of the Harveian Society, to-morrow evening.

DR. G. P.—The announcement is inserted.

CAVENDO.—If A. attended the patient for B. while the latter was out of town, and at the request of B., there can be no doubt as to the person to whom the patient belongs; and even if B. did not request A. to attend, A. ought, in courtesy, to give up the patient when B. returns.

A FIRST YEARS' MAN.—It is impossible to give a concise answer to the question, as it involves a great amount of chemical theory, but the hydrogen scale is the easiest to remember.

J. S. (Mile-End).—We have alluded to the subject in another part of the Journal.

QUÆSO.—The name does not appear in the 'Directory,' and the whole affair looks rather suspicious.

THE NEW FOOD FOR INFANTS.

A SUPERIOR FORM OF BARON LIEBIG'S FOOD,

SPECIALLY PREPARED BY

SAVORY & MOORE,

Chemists to the Queen, H.R.H. the Prince of Wales, and His Majesty the King of the Belgians.

NO BOILING OR STRAINING REQUIRED.

REPORT UPON SAVORY AND MOORE'S FOOD FOR INFANTS AND INVALIDS, BY DR. HASSALL.

"I have subjected the food prepared by Messrs. Savory and Moore to full examination and analysis, in both its uncooked and cooked conditions, and I find it to be eminently adapted for the food of infants and invalids, being highly nourishing, and, what is of the greatest consequence, of easy digestibility. It is essential that the instructions given for its preparation should be closely followed, the conversion of the starch into dextrine and glucose, whereby the food is rendered so much more digestible, depending upon the action of the diastase contained in the malt flour—one of the constituents of Liebig's food. The activity of this principle is destroyed at a temperature of about 150° Fahrenheit; it is, therefore, very necessary that the heat employed in the preparation of the food should never exceed that degree; indeed, it is best not to allow it to pass beyond 148° Fahrenheit, a temperature amply sufficient to break up the starch corpuscles, as may be readily seen on microscopic examination, and, therefore, to cook the food sufficiently without having recourse to boiling.

"As temperature is of so much importance in the preparation of this food, I recommend that a thermometer be in all cases employed; and, in order to ensure greater uniformity in the strength of the prepared soup, that the quantities of the dry food, milk, and water used should be determined by means of a little dry measure cup, and a graduated glass for the water and milk.

"ARTHUR HILL HASSALL, M.D. Lond.,
"Author of 'Food and its Adulteration;' Senior Physician to the Royal Free Hospital."

Sold in Tins, 1s., 1s. 6d., 2s., and 5s. each.

SAVORY and MOORE, NEW BOND-STREET. | FORTNUM and MASON, PICCADILLY.
DUNCAN, FLOCKHART, and CO., EDINBURGH. BEWLEY, HAMILTON, and CO., DUBLIN.
Wholesale: BARCLAY and SONS; CROSSE and BLACKWELL; EDWARDS and CO.; NEWBERY and CO.; and Wholesale Druggists generally

BARON LIEBIG'S EXTRACT OF MEAT, (Extractum Carnis.)
Imported by SAVORY & MOORE.
In Original Packages of 5lbs., 1lb., and ½lb. each.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, IS Mr. WILLIAM LAWLEY'S, 7S FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.—Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments forwarded for 6 stamps

Brass and Zinc Door-Plates.—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges. Chemists' Shops fitted up with Window-sill Plates in the plain or O.G. Patterns. Lists of Prices post free.
Plates altered and repaired.—Country orders punctually attended to.
36 CHANDOS STREET, CHARING CROSS, W.C.

Kamptulicon, Floor-cloth. — The attention of the Medical Profession is requested to be given to the many advantages of this article as a floor covering, for the Wards of HOSPITALS, Surgeries, Nurseries, &c. It is non-absorbent, quiet, and warm to the tread, will not hold dust, is very easily and quickly cleaned, and will stand any amount of hard wear. It has already been adopted in several hospitals.
GOUGH and BOYCE, 76 CANNON STREET WEST,
Original Patentees and Manufacturers.
Forwarded to all parts of the Country.

Treloar's Kamptulicon,
COCOA-NUT MATTING,
AND OTHER DURABLE FLOOR COVERINGS,
67 LUDGATE HILL, LONDON,
Three doors from the Railway Bridge.

Geo. Smith and Co.'s Pure Extract of CALVES' FEET for INVALIDS and CULINARY USE. Sold in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Druggists, Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland-street, Regent-street Office: 94 Upper Thames street, E.C.

Medical Fixtures and Glass Manufactory, 3 Liverpool street, Bishopsgate, London.
FILMER KIDSTON begs to inform Gentlemen Commencing or Assisting in the above Profession, that he has an extensive assortment of HOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc

H. Silverlock's Medical Label Warehouse, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctor's Commons, London, E.C.
DISPENSING LABELS, for the use of Surgeons.
YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.
SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.
LABEL CASES for the use of Surgeons, 14s., 18s., and 24s.
LATIN SLIP LABELS for Wholesale Druggists.
Catalogues sent on application.

William Hawke, Wild Court, Great WILD ST., DRURY LANE, LONDON W.C., (late Ansell and Hawke), Manufacturer of every description of Shop Fittings, Dealer in Medical Glass, Earthenware, and all kinds of Shop Utensils, Machine Labelling, Writing, and Embossing on Glass.
Drawings, Specifications, and Estimates furnished for Fitting-up Druggists' Shops and Surgeries with every requisite, and for erecting Shop-fronts. Druggists' Stocks and Fixtures valued.

J. Clarke (late Thompson), Surgical Instrument Maker, Cutler, Truss and Bandage Maker, 225 Piccadilly, near Regent's Circus, W.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

FEW PRACTICAL REMARKS ON HERNIA, ECZEMA, AND AFFECTIONS OF THE HEART, OCCURRING IN THE AGED.

By Henry Samuel Purdon, M.D.,
L.R.C.P. Edin., L.R.C.S.I.

sistant Physician Belfast Charitable Infirmary and Institution, Physician Belfast Dispensary for Diseases of the Skin, and Academy Street Dispensary for Affections of the Chest, late Medical Officer Templepatrick Dispensary.

rnia is the first disease that I shall briefly consider, and deavour to point out some of the peculiarities of this ection occurring in old persons. The commonest form hernia to be met with amongst the inmates of the Belfast aritable Institution, is the oblique inguinal, all other nds being rare. On a rough estimate, one man in eighteen s this complaint, which has usually existed for some rs before admittance into the Institution.

As it is not my intention to enter into a consideration of anatomical characters, symptoms, &c., of hernia, and as vish to be as brief and practical as possible, I shall only ntion the following peculiarities and treatment:—

When a rupture has existed for some years, it is usually her difficult or impossible to return it, for the following sons: the abdomen has become accustomed to its diminished contents, and if the surgeon does succeed in returning the hernia, colic, vomiting, and other unpleasant symms frequently obliges him to allow it to descend again; eed, cases have been recorded by Petit of this practice ving fatal, probably from peritonitis. Increased volume the hernia may likewise prevent it being returned, or esions to the sac, and thickening and enlargement of the entery or omentum. For the above reasons, to return a standing rupture is rarely tried, the great danger to be id of is strangulation, and the great object is to guard nst this; so that when any symptoms of pain or unness in the rupture arise, the following treatment is at commenced, and has now been in use for the last five x years, being first suggested by Dr. Ferguson, surgeon his Institution. Cloths steeped in vinegar and cold r, or a refrigeratory mixture such as one composed of te of ammonia and nitrate of potash are constantly ied, the patient being given a cup of the strongest in- m of coffee, with very little sugar and milk, every half- r. This plan of treatment has been found very successand in reducible hernia, which before would not stay return after a few cups of coffee with the greatest ease, remains up. One thing about the coffee is, that it contain no chicory.

Joseph Gammat, in 'Braithwate's Retrospect,' Vol. VII., mentions a case of hernia in which the sym- s of strangulation appeared, and after trying the taxis, vithout success, he gave a strong infusion of coffee (3j. ie cup), and after the first cup he reduced the hernia ut trouble. The following case illustrates some of ffects of coffee:—

n Dyer, aged ninety-two, an inmate of the Belfast table Institution, in height about 6 ft. 2 in., had no e but hernia, complained of symptoms of strangula- n September 29th, 1865.

tory.—Was formerly a carter; his rupture has existed out twenty years, unpleasant symptoms have occaly arisen; wore a truss irregularly for about six

sent condition.—The hernia is of a very large size, ling about half-way down the thigh; bowels regular; appetite good; complains of pain and uneasiness at seat of rupture.

Treatment.—To have a cup of strong infusion of coffee every half-hour, also a refrigeratory lotion applied to the scrotum.

October 2nd.—Much better; complains of no pain; coffee has been discontinued.

October 5th.—Is up, and to all appearances quite well; complains of no unpleasant symptoms; bowels regular. This treatment has been before pursued on several occasions with this patient, and has always been found to succeed both in his case and that of others.

Eczema.

There is a curious form of eczema, which I think is peculiar to old people, occurring principally on the legs, and, as far as my observation goes, most common in winter, which I attribute to sitting too close to the fire. From the appearance of this affection, it might at first glance be mistaken for erysipelas; the skin of the leg is red and glazed, combined with œdema of the ankle: the affected surface also pits on pressure, and is not very painful to the touch; but any effort at walking is rather painful: a feeling of burning heat is complained of more than itchiness.

This form of eczema is one of the most difficult to cure. As regards constitutional treatment, I usually give the tinctura ferri perchloridi in doses of fifteen drops, gradually increased to twenty-five, three times a day, combined with the occasional use of an aperient pill. If the patient is not much debilitated, Fowler's solution may be prescribed with the tinct. ferri perchloridi. The local treatment is to my mind more important than the constitutional, and in the acute stage I think nothing answers so well as the linimentum calcis, to which a little camphor may be added. The cold water douche in this stage is also useful. The linimentum calcis should be used constantly until the acute stage has passed, which is known by scales forming, which are frequently of a laminated character; a sensation of itchiness is often complained of at this period. When the sub-acute stage has commenced, the vapour of sulphur and iodine (3iij. of the former and ten grains of the latter) is to be applied to the affected surface, as recommended by Dr. Burgess, who suggests the following method:—A common can, large enough to hold the leg and foot, is to be obtained, in the bottom of which a hot iron is placed, upon which the sulphur and iodine are laid, of course protecting the foot from the iron; the leg and can are then enveloped in flannel, and the leg may be kept in about fifteen minutes. If the disease is of a more chronic nature, I am in the habit of using an ointment made of tar, castor oil, carbonate of potash, and white wax; this ointment, which is to be used night and morning, and rubbed firmly into the affected surface I have now used for some time. What first led me to combine these ingredients, may be learned from my paper "On Cases from Practice" in the Medical Circular for April, 1865.

Disease of the Heart.

The commonest forms of disease of the heart are softening and dilatation, with thinning of the walls. As the symptoms of these diseases are familiar to all, I hope to be excused for saying a few words on dilatation occurring in the aged, and a probable cause of this affection. Now, I do not intend to commence a crusade against tea, as it is a beverage of which I am very fond; but, nevertheless, its immoderate use evidently occasions affections at least of the stomach and heart. In the former organ, its use gives rise to various forms of dyspepsia, the nature of which, if entered into, would be foreign to the object of this paper.

As regards affections of the heart caused by tea, I am borne out in my assertion by the high authority of both Drs. Williams and Stokes; the former in his work 'On Diseases of the Heart,' and under the head of 'Functional Palpitations' remarks: "Everyone knows that the habitual use of strong green tea, is apt to excite constitutional disturbance of the heart, often amounting to paroxysms of severe palpitation." Dr. Stokes also relates several cases of various affections of the heart arising from the immoderate use of tea. Now, it must be evident that if the use o

tea be further indulged in, organic changes in the structure of the heart must take place sooner or later, and these changes I attribute, especially as regards dilatation, to the tannin contained in the tea acting primarily on the mucous membrane of the stomach, and subsequently through the sympathetic system, on the heart, weakening its muscular fibres. For further remarks on the action of tea on the teeth and its physiological effects, I must refer to a paper of mine on this subject in the MEDICAL CIRCULAR for February, 1865.

As regards treatment, tea should be either given up, or its use limited to one cup for breakfast and one for supper. The remedies most useful are the various preparations of iron, and for hospital use the sulphate answers very well, and I am in the habit of prescribing with it the extract of nux vomica, and which has an excellent effect.

EPIDEMIOLOGICAL SOCIETY.

CHOLERA.

MEMORIAL TO THE FOREIGN OFFICE.

The Epidemiological Society, which was founded at the beginning of 1850 for the study of Epidemic diseases, not only at home but also in foreign countries, has had their attention directed in a special degree to the investigation of Malignant Cholera. No pestilence in ancient or modern times has had a wider or a more destructive range over the face of the globe, since its first great migratory movement, which commenced now nearly fifty years ago. After ravaging India, it spread in all directions, so that scarcely a country in Asia during the next few years escaped, from China to the Ural Mountains, and from the Indian Ocean to Siberia. After occasional lulls and intermissions in its progress, it at length reached the confines of Europe in 1830-31, and then steadily advanced in its westerly course, chiefly through the central part of the Continent, until it appeared on our shores in the autumn of the latter year. In 1832-33 America was attacked; and during the next three or four years the southern countries of Europe bordering on the Mediterranean seem, as far as our imperfect information enables us to determine, to have been the principal seat of its ravages.

After 1837 Europe was, it is believed, free from the pestilence for the next nine or ten years, when a second great epidemic wave or current, so to speak, again set in from the remote East, and passed over Europe and onward to America in 1848-49. This visitation was both wider spread and more disastrously fatal, alike in Europe and in the New World, than the former epidemic.

The interval between the cessation of this epidemic and the following one was much shorter than on the previous occasion; it did not exceed three or four years at most, and, indeed, it is doubtful whether the germs of the disease had ever become thoroughly extinct or annihilated in Europe and America.

The epidemic at present existing along the shores of the Mediterranean is generally supposed to have commenced in or near to Alexandria during last June; but no reliable data have been obtained respecting the circumstances or conditions under which it manifested itself in Egypt, and whether it had been previously prevailing— and if so, for how long—in Mecca or other parts of the Arabian peninsula. Most imperfect, too, is the intelligence as to the earliest occurrence of the disease in many places which have been already attacked, more especially in Syria, the islands of the Archipelago, and the Adriatic coast of Italy, &c.

Hitherto, the information before the Profession respecting the exact course of the development of Cholera in the several epidemics which have traversed Europe has been far from being either so correct or so complete as the interests of science demand. A much more full and accurate knowledge of the geographical history of the disease—as it appears in different lands, and under the varying conditions of climate, country, the habits and diet of peoples, &c.—is greatly to be desired. Epidemiological inquiries have to be conducted in much the same way as meteorological inquiries; to be fruitful of good, both must equally rest on accurate data collected in a wide area of observation, and over periods of time more or less extended. What the Board of Trade now does to advance the progress of meteorological science may be done by other departments of the Government to advance the interests of epidemiology.

On no point is authentic information more needed than as to the exact dates when the pestilence first appears in the different localities attacked over the face of the continent. Great Britian possesses greater facilities in obtaining such information, from her wide spread relations and intercourse, than most other countries. It is respectfully submitted that the object in view might be efficiently attained, through the co-operation of H.M. Consuls, if the Secretary of State for Foreign Affairs would be pleased to give instructions to those gentlemen to record and communicate the most reliable information within their reach in respect of their consulates and the surrounding districts, and if all such information were made available for the benefit of Medical science. To the following points the Council of the Society would particularly invite attention—

1. The exact dates of the earliest recognised or ascertained cases of the disease, whether the cases proved fatal or not.

2. Did these cases occur among strangers or persons recently arrived in the place?—or among residents who had not been recently away from it?

3. Had there been any unusual amount of bowel disorder, or other form of sickness, prevalent among the inhabitants prior to the occurrence of these cases?

4. In what part of the town or village did the first cases occur?—and what part or district suffered most during the visitation?

5. What is the nearest place where the disease was known to exist at the time of the occurrence of the first cases, or to have existed shortly before such occurrence?

6. What precautionary measures have been taken by the authorities to avert, or to meet, the visitation?

GAVIN MILROY, M.D., F.R.C.P, *President.*
J. N. RADCLIFFE, *Secretary.*

September, 1865.

THE LATE MR. McNAB AND THE CHOLERA AT EPPING.

In the course of the illness of Mrs. Groombridge and her daughter, Mr. McNab and Mr. Duncan McNab had been personally unremitting in their attendance. They neither of them suffered during this time; and Mr. Duncan McN. has not suffered at all. On Sunday, October 1, Mr. McN. sen. was quite well, and at noon of that day he also attended the Groombridge family. On Monday, October 2, he took a long round of patients, and was particularly cheerful. In the afternoon he dined at 6 p.m. At about 7 p.m. he retired to his study, and fell asleep in his arm-chair. At 8 p.m. when called for tea, it was found he had gone up-stairs, and was sleeping on a sofa. He slept until a little before 9, when he woke up and immediately vomited. The housekeeper, who call him, remarked that the chair and sofa on which he reclined gave out a peculiar odour, as of must, which had not been noticed before. Mr. M'Nab, jun., was at once sent for; and on his arrival he found that the patient himself had prepared a mixture of chalk and opium, which was taken but at once rejected. At eight minutes past nine he was vomiting constantly, and passing rice-water evacuations by the bowels. Cramps soon followed, and much prostration. Attempts were made again to administer remedies to him; but everything was vomited as soon as taken. Mr. Duncan M'Nab then left for a brief interval to fetch some new remedies. On his return, the patient was cold and the skin clammy; the tongue shrunken, white, and also cold. It was peculiarly noticeable that early in the attack the chin of the patient was extremely cold—it was like ice; then the nose and forehead followed in the same way. There were no local spasms, and

kind of general spasm of the whole muscular organism, hich absorbed, as it were, the local manifestation of mus-ılar contraction. The chief fluid that could be tolerated as wine, and this was given freely; but, as the sufferer mself said, it did him no good. He died in the early part the morning of Tuesday, October 3, within ten hours of e period of attack.

The symptoms were so urgent that no internal remedy s retained, Externally heat was applied, and it seemed, h relief. The extremities were never extremely cold; t the veins presented a peculiar dark, conjested, and pro-nent appearance as if the blood had coagulated in them ring life.

Let us hesitate here for a moment to say one gentle word pecting this excellent man, Mr. Daniel McNab, who s fell. He was a fine specimen of a true-hearted Eng-ı Medical Practitioner, a hard-working Practitioner of good old country school. In youth he could hunt with best, and could practise physic none the less satisfac-ly. In manner sociable, in action courteous, in busi-s punctual, in deed honourable, he won his way with who knew him, and gained reliance where less gifted ı only gain acquaintance. This influence extended not ngst patients alone but amongst the members of his ı Profession, many of whom in early life, acting under as their master, have been followers of his teaching successful largely by his example. He had a deep of science, and was profoundly interested in the nt advance of Medicine; but his great friend, coun-or, and philosophical guide was the mystic fascinator, anuel Swedenborg, whom let any one follow and he t obey.

he last glance at the life-history of Mr. McNab is sin-rly and solemnly beautiful. We can conjure up easily busy country doctor, starting in the heyday of youth, ng from morning till night, leaving no work undone, going home to sleep six or eight hours in one short and then up again at work until position is secured his name well known for miles around. We can see in his prime, with pupils and assistants around him, he centre of an active circle, keeping up the work by nple, and sharing with the others in labour: and we follow him gradually down the decline, still active but ng that night work must be given up and the heavier es. All this is common experience; but when we arrived at this point of decline in the life of Mr. ab, we behold rising before us a new picture. He has d from work, and indulges, as he ought, after a ge of threescore years and fourteen, in learned leisure. ven that leisure is so toned that it enables him to live or work and duty. If wanted, though on his part it reak on his well-earned rest, he is always ready; and happens that on September 30, 1865, a little child contagious disease must be visited by him. He gives is ease to be her succour—takes from her the death , and follows her, still in the path of duty, to the

historian may use romance for his effect, or dig up legend the roll of brave deeds on land and water—tle-field and peace-field alike—but he shall not find er picture than the picture of this well-worn and yet soldier of the Esculapian brotherhood, going out, white locks and gentle heart, to see that suffering He knew that in the act there was not a picking of he world calls fame and glory; but there was a duty done, though death should seal it. It is in deeds ese that Medicine shines forth so divinely. It was death this of our brother—a death to be envied, not ed over; and the sneering world, taking courage t, may gain faith that the profession of physic is not lost yet. "Can a man do more than die for his ?"—'Medical Times and Gazette.'

ZOOLOGICAL GARDENS.—Two of the remarkably ills and one of the cows presented by King Victor el to the Zoological Gardens, fell victims to the plague on Wednesday last. A cow and calf still ı.

"CYCLOPS'" TWENTY-FOURTH LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—Our inquiry must now be directed to the colon itself. As there are so many good descriptions of its anatomy in appropriate works, it needs only reminding the reader of its peculiarities as compared with all other viscera. Thus the cæcum is the first portion of it to receive all solid matter from the small intestines, and shut it off immediately from all its former tracts by the ileo-cæcal valves, and so the fæces become exactly what they are—namely, excrementitious matter, and there is no longer anything therein to be digested, nor do they contain any nutritious elements, but are completely excluded from all further acts of their kind in the body, as we may imagine the contents of a sink or cesspool outside a house. In fact, both are got rid of in much the same way, and cast into separate departments, as no longer necessary, but rather an offensive matter if allowed to remain where they were first generated. In investigating the character of the colon, we find that its muscular fibres are longitudinal, and all tied together by a common band running through its entire length; so that what we ought to expect, we find reversed, for this reason, that if they had been circular bands and fibres, these would contract upon the contents of this viscus, and so assist in propelling them, whereas the reverse is clearly evident to all anatomists and physiologists. Hence, as I have said in a previous letter in explanation of the peristaltic action of the bowels, there cannot be any action of this kind in the colon, and I deny emphatically that there is. Its very anatomy bears me out in this opinion, for that which would have assisted progress —namely, circular fibres to its muscles and peristaltic action, are both absent, the one as a fact, the other as a law. We can come, then, to no other conclusion but that detention is the object Nature had in view, which is further proved by the fact, that rather than allow these abominable and disgusting fæces to pass away too quickly, she would sooner allow them and their gases to distend the viscus, as she often does, and so it frequently becomes, at various parts, in a very sacculated condition. This commences even from the very first part—namely, the ascending portion.

Now, this is the hill that is to be travelled first by the fæces, on the principle of the vis a tergo. Arriving at a point about a third or middle of the liver, on which it presses and resting in its ascent on the right kidney as well, it takes a turn and becomes what anatomists call the transverse arch of the colon. Here, again, is a curious arrangement by which this part of the common sink or cesspool of the body is made to rest on the duodenum, and partially on the pancreas as well as against the lower part of the stomach. It is partly covered by peritoneum, but some of its posterior portions are not. Here the fæces, after having mounted perpendicularly, are pushed along horizontally. The same law apparently regulating this part of the viscus, that instead of hastening them along it, its calibre is often distended, which necessarily retards their progress. What an odd thing for Nature to do! but we must look facts in the face. At the end of this gallery there is a turning point or corner resting on the spleen, and thus we come to the descending portion, which rests very shortly at this part on the left kidney, so that there is hardly an abdominal organ that this filthy sink does not touch, or rest upon, or is contiguous to.

Now, this descending portion is shorter than the ascending, and very soon gets to the sigmoid flexure, which is nothing more nor less than a treble turnpike gate. This singular formation illustrates a curious fact, which is, that instead of the fæces resting on parts pointing downwards, it rests on three distinct horizontal lines, precisely as it does on the transverse arch. We may presume that it has no difficulty in passing round the four corners that are made by this arrangement of a letter S turned on its side. But getting over the last, the fæces pass into the rectum. Now here, again, instead of being a straight gut it is a curved one, which may be divided into three parts, and we shall find the same law occurring here; that as fæces get into the upper third, they rest, not upon the point pressing vertically upon

the second third, but on a bend. Again, when they reach the centre third they do the same, and when they get into the third division, the same fact obtains there also. If this was not the case, they would drop at once perpendicularly upon the sphincter ani. But the natural anatomical provision has rightly guarded against this, and for this reason, that a longer or shorter detention at each of the three curves is necessary. Hence, from this arrangement, the fæces in their ordinary state are under the will of every individual. It does not follow, that when fæces get into the upper and centre third of the rectum, that there ensues a hint from the electro-nervous batteries in that part, of the desire to get rid of them, because they may remain some time in the two upper thirds, and no notice given to the owner that it is necessary for him to prepare for the act of defæcation. It is only when they get into the third and last part that this notice is duly given. So that we see from the first moment to the last, throughout the whole of this tube, that every opposition is offered to the passage of the fæces through it, even in a natural way, when the individual is in perfect health. But when he has a departure from this state, we find that Nature assists this act by distending given parts along the line and making sacculated portions for its use.

Now many would consider that this was a diseased condition. Let them think a while, and they will learn that it is a process designed by Nature for curative purposes—for purposes of life and health. All these anatomical arrangements are worth considering more deeply than they have ever yet been done. Anatomists have shown how all these parts are supplied with their due and proper arteries in order to keep up their structure, not their secretions or any other matter physiologists have set forth, for I have in former letters denied that the blood supplies anything but elements of structure, and that it has no power to supply secretions to organs as well, nor a tithe of the lubricating fluid elements which the body uses daily to a great extent. Let us give the colon from end to end all the arterial currents which anatomists have seen to go to them. Let us take the veins, as books have recorded them, as well as the nerves which supply them from their several varied sources. All these facts have only to do with the upholding and general nourishment of this viscus, but nothing whatever with the acts of the colon itself, or the usefulness of its contents.

We have seen that little or no oxygen gets into the colon along with the fæces, and therefore we must naturally suppose that the emanations from the fæces resemble pretty much those of a common cesspool, and which in fact they do. Its gases are all of the most poisonous character, for they are rich in all the hydrogens, mixed with the sulphuric and phosphoric, and having nothing to prevent their formation, must have their full delight and revel in this human sink. It is the knowledge of this that has led the Faculty to be greedy of the expulsion from the system of such a mass of filth. Yet if we look at the perfectly healthy individual who gets his regular morning action of the bowels after breakfast, we might think that he empties the whole of his colon in that act; but he does no such thing. Nature is too wise to allow anything of the kind; he only gets rid of what there may be in the rectum, in the sigmoid flexure, and part of the descending colon. Abhorring a vacuum she retains two-thirds—namely, that which is in the transverse and ascending colon and cæcum. So that, in fact, the colon is kept always two-thirds full, and once in every twenty-four hours it is quite full. We necessarily infer, therefore, that the fæces are constantly generating these foul and poisonous gases, and by the wise law of exosmose, these, being principally hydrogens and very light in their character, must permeate the porous structure of the intestines, and find their way throughout the whole of the body.

Now, there is at this time much said of free air, good ventilation of rooms and buildings, a given quantity of cubic feet of free oxygen to every individual, four hundred at the lowest for his actual necessities, for when there is less and numbers are congregated in one apartment, this room becomes a fever or typhus den, which it often does. The opinion is, that the fever or typhus is produced through want of due ventilation, or a proper quantity of pure oxygen. Now this I demur to. It puts me in mind of a friend of mine who frequently has to complain to his wife of one of the breast buttons of his shirt always coming undone. He declares that the button is too small for the button-hole, and she as stoutly maintains that the button-hole is too large for the button. This is just the case in point. Some declare that the want of oxygen causes the fever and typhus, while I maintain that it is the poisonous elements from every individual's own body. But, says the hygeist, if there had been proper quantities of oxygen, these poisonous elements would have been in some way neutralised. Just so; but then, the poisonous elements are always there, and that the fever and typhus are due to their being in excess, and not neutralised, they poison, and so the argument might go on. While on the other hand, man gets certain classes of diseases entirely through the absence of these poisonous elements, and he could not have health without them. Nature having fully provided for the fact of their being made and afterwards using them in her own way, we have to find out why an incessant exosmose of these poisonous gases permeates the whole body, and more particularly the tissues and interstitial spaces, and by these inquiries we shall find a clue to the regular actions of the bowels in some persons, the conservatism of constipation in others, and the laws which obtain, that in many diseases, if left to themselves, that is, to Nature alone, they are cured by these wise acts and laws. So that we have to prove their relative value in the system, and why they are so useful in health, and that we could not have health or even life without them. And we have further to demonstrate that they are the means of producing many fluid elements in the body, which the body could not do without, and which neither the blood can supply nor any other form of secretion from any other source. And not only this, but that some very important solid matters and structures of the body are also due to their presence, as well as many natural diluents of which I have spoken in previous letters, which the blood never supplied and never could supply, and what is more, would never in any quantity become a part of the great circulating medium itself.

I am, &c.,

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. T. K. CHAMBERS commences a course of Three Lectures "On the Effects of the Climate of Italy," the present lecture being chiefly devoted to the record of his personal experience. It will be recollected that about a year and a half ago, Dr. Chambers underwent the operation of amputation of the leg on account of degeneration and rupture of the popliteal artery. Some months afterwards, he endeavoured to resume his practice, but found himself not equal to the task, and by the advice of friends, he went away from London for about a twelvemonth. He has now returned, and it will be gratifying to all to learn that he comes back, in his own words, "with restored health and strength, and by God's blessing, enabled to engage actively in the duties of the Profession." Most of the time of his absence was spent in Italy, and in reference to the diseases most prevalent in that country, Dr. Chambers remarks that acute diseases are far more common than the chronic, and he was informed by an Italian physician, who had practised in Rome, that he had ninety-five acute cases to five chronic. The greater part of the present lecture, however, is devoted to the consideration of the symptoms of degenerative disease, or what is generally known as "

ıealth," where there is no special injury to a particular ırgan, but a general deterioration in the tissues.——Mr. Berkeley Hill gives a description of the "Initial Lesion f Syphilis as observed when Inoculation of that Disease ; made Experimentally." In the present paper, Mr. Hill rings evidence, from his own observations and the writings f others, that ulceration is not necessarily the earliest or ıe immediate consequence of syphilitic inoculation.——)r. W. R. Sanders commences a paper "On Facial Hemiegia and Paralysis of the Facial Nerve." There are two ıuses for this affection—namely, either some cerebral sion, or some affection of the trunk or branches of the ortio dura itself. In cases of facial paralysis due to a rebral lesion, the late Dr. Todd argued that the motor anch of the fifth pair was the paralysed nerve, but Dr. nders shows both from the writings of Dr. Todd himself, d from the evidence afforded by living cases and by postrtem examinations, that the facial branch of the seventh the injured nerve. He states that in the living cases, the sseter, the temporal, and the two pterygoid muscles ıich are all supplied by the motor branch of the fifth r), were unaffected, although the action of the buccinator ıich is supplied both by the branch just mentioned and the facial nerve) was impaired. The same fact was explified by the post-mortem examination of a case of miplegia depending on cancer of the brain.——Dr. HARD Holt, of Hitchin, relates a "Remarkable Case of rbus Addisonii," the patient being a man of middle age, whom the disease developed itself without any assignable se. The usual blackening of the skin was observed and s accompanied by great prostration, and the patient dually sunk. After death the supra-renal capsules were nd extensively diseased, the left being completely disorıised and converted into a kind of bag filled with a thick lowish fluïd, containing a number of fragments reıbling in appearance and consistence the white of a d-boiled egg.

The 'Medical Times and Gazette.'

)r. George Harley continues his lectures "On the ne and Diseases of the Urinary Organs." His present ject is the pathology of diabetes mellitus, and he uces cases to show that saccharine urine may be proed by various diseases and injuries of the brain, also by ıtal excitement and by disorders of the digestive system, even by the use of certain articles of diet. A man ught into University College Hospital died apoplectic, on post-mortem examination a clot of blood was found he medulla oblongata, and the urine was easily shown e saccharine. In other cases, injuries to the head have luced diabetes, which disappeared with the recovery of patients from their accidents. The greater prevalence liabetes in this country as compared with the continent tributed by Dr. Harley to the greater consumption of holic drinks in Great Britain. The injection of stimufluids into the system of some of the lower animals been followed by diabetic urine, and Dr. Harley found r in his own urine after eating asparagus. He considers a comparatively insignificant cause may induce etes in a predisposed constitution.——Dr. C. R. Bree, Colchester, offers some "Remarks upon the Address in icine delivered by Dr. Stokes at the Leamington ting of the British Medical Association for 1865." In these remarks, Dr. Bree strongly opposes the theory propounded by Dr. Stokes as to the change of type in disease, and argues that the change of practice in modern days is attributable to the more enlightened views now existing as to the nature of disease in general, and he concludes that the physicians of the last generation were altogether mistaken when they recommended bleeding and other so-called antiphlogistic measures in the treatment of fevers and inflammation.

The 'British Medical Journal.'

J. L. Bidenkap, of Christiania, offers some "Remarks on the Unity of the Syphilitic Virus." He admits, in the first place, that the larger number of primary venereal sores do not produce constitutional symptoms when left to take their natural course, or at least when they are treated only by local non-specific remedies—namely, when mercury is omitted. Hence has sprung up the theory of the duality of the venereal poison, and Bidenkap does not deny that there is practically a marked difference in the development and characters of the two kinds of disease, but still he contends that they spring from one source, the differences depending only upon accidental circumstances. Even those who hold the dualistic theory admit certain exceptions to the rules they lay down as to the characteristic features of each form of disease, and these exceptions they explain upon the theory that there exists what is called a "mixed chancre." But Bidenkap maintains that this latter form of chancre, instead of being an exception to the rule, is really the typical form of the disease, and that either variety may be produced from it. He then goes on to show that, in his opinion, almost all chancres are inoculable, if the operation is properly performed, and when it does not succeed it is because the inoculation is performed before suppuration has commenced. He therefore recommends that inoculation should be repeated day after day until the pustule appears, and if other means fail, the application of powder of savine to the surface of the chancre will often hasten the result. Bidenkap then adduces some cases observed in practice, which, in his opinion, prove the truth of the views he maintains as to the unity of the syphilitic virus.

REVIEW OF BOOKS.

Orthopraxy: the Mechanical Treatment of Deformities, Debilities, and Deficiencies of the Human Frame. A Manual. By Henry Heather Bigg, Assoc. Inst. C.E., Anatomical Mechanist to the Queen and Prince of Wales. Pp. 709. London: Churchill and Sons. 1865.

The meaning attached by Mr. Bigg to the newly-coined word Orthopraxy, is sufficiently explained in the title of the book; but the adoption of the word is further justified and defended in the early part of the Introduction, where it is described as being synonymous with mechanical therapeutics, or the art of making things right (*ορθος* straight, right, *πρασσω* to make) which have gone wrong, either by accident or disease. For this art, Mr. Bigg claims recognition as a distinct branch of Medicine, or the art of healing, and in a very able historical summary he traces the progress of orthopraxy from the earliest period to the present time. He shows that Hippocrates was the father of mechanical therapeutics as well as of Medicine, for he published in his book on articulations an account of the nature and mechanical treatment of incurvation of the spine and club-foot, and it is a curious fact that the terms he employed to

designate the three spinal curvatures, namely, *cyphosis*, *lordosis*, and *scoliosis*, are those in use at the present day, and are employed in pretty nearly the same sense. After quoting some passages from Hippocrates on the subject of the relief of deformities, and presenting some amusing pictorial illustrations of the rough but ingenious methods of treatment adopted in ancient times, the historian of orthopraxy makes a leap forwards from Hippocrates to Ambrose Paré, whose contrivances for removing or relieving deformities are highly creditable to his ingenuity, although he often supplements the use of mechanical aids with nostrums suggested by his fancy for their supposed efficacy as external applications. After Paré, Fabricius Hildanus, Scultetus, Glisson, Heister, Andry, and others, successively contributed to the progress and success of orthopraxy, till we arrive at the end of the last century, when Mr. Sheldrake, who was the predecessor of Mr. Bigg's father, published his work on what would now be called orthopædy, or the treatment of children's deformities. During the commencement of the present century the art made still further progress, and advanced with equal strides together with surgery, the introduction of tenotomy for the cure of certain deformities, by Stromeyer, having in 1834 introduced a new era in surgical therapeutics.

After this historical account Mr. Heather Bigg proceeds to the more immediate object of his work, namely, the discussion of the mechanical treatment of deformities, debilities, and deficiencies of the human frame; and those who are aware of the great power possessed by modern art in this direction, will be able to estimate the number, the interest, and the variety of the subjects introduced to the notice of the reader. On the principle that visible representations of the apparatus described are calculated to impress the memory far more than mere verbal disquisitions, this part of the work is profusely illustrated with well-executed drawings of every mechanical appliance mentioned in the text.

Mr. Bigg's handbook is a most useful summary of the art which it is intended to describe and exemplify, and its materials are arranged with great ability and even learning.

Pure Dentistry, and What it does for us. By A Eskell, Surgeon-Dentist. Pp. 73. London: Clements. 1865.

Pure Dentistry is defined by Mr. Eskell as that division of the art which is founded upon science and experience, as contra-distinguished from that which is merely mechanical and empirical; the former being often able to cure and save, while the latter may injure or destroy. He justly observes that judicious extraction of teeth may often confer great benefit, while the inopportune performance of the operation may not only sacrifice one tooth, but weaken and injure the others. He also refers to the numerous instances of local and general disease which are traceable to irregularities or decay of the teeth, and he argued that a due attention to these organs, removing them when decayed, and repairing their loss by mechanical substitutes is often attended with the most beneficial results to the general health. Mr. Eskell's little work will be perused with advantage.

A Practical Treatise on Rupture, its Causes, Management and Cure, and the Various Mechanical Contrivances Employed for its Relief. By T. P. Salt, Birmingham, Anatomical, Surgical and Orthopædic Mechanician. Second Edition. Pp. 112. London: Churchill and Sons, 1865.

Although entitled a Treatise on Rupture, this work emanates from a mechanician whose chief object is to point out the various instruments employed for the relief of inguinal and femoral hernia and of prolapsus uteri and prolapsus ani. But several descriptions are given of the anatomical details connected with these displacements, and illustrative diagrams are also introduced; all which are superfluous to the professional reader, and must be, we imagine, either unintelligible, or insufficient to a non-professional one. Still this little book contains some useful information, and the different forms of instruments are well described and their use briefly indicated.

The Vaccination Acts: with Introduction, Notes, Cases, Instructional Circulars, and Index. By Danby P. Fry, Esq., of the Poor-law Board. Second Edition. Pp. 84. London: Knight and Co., 1865.

However much we may disapprove the plan of leaving the machinery of public vaccination to be worked by the Poor-law Guardians, we cannot but commend the object of the present little work by Mr. Fry, who has collected together all the Acts of Parliament referring to this important subject, and has prefaced them with an introduction which gives a concise summary of the object and purpose of each legislative measure. Mr. Fry has conferred a boon upon all public vaccinators by offering this compendium to their notice, and the appearance of a second edition proves how much the first was appreciated.

THE CATTLE DISEASE.

The Lord Provost of Edinburgh has, in some measure, anticipated the royal commission, by giving publicity to an *ad interim* report which he had received from the Medical committee, lately appointed by the magistrates of that city to investigate the causes and symptoms of the *rinderpest*, and the means of prevention and cure. His report, signed by Dr. Andrew Wood, the chairman, and may be regarded as embodying the best available skill of the Medical and Veterinary Colleges of Edinburgh. The following is an abstract of its conclusions:—

"1. That the disease is communicated by contagion from diseased to healthy cattle, and apparently by contagion alone. 2. That the poison of *rinderpest* is a specific poison which filth may intensify, but cannot generate. 3. That the question whether the contagion can be propagated by inoculation remains to be tested. 4. That the poison, as in other zymotic diseases, is introduced chiefly by means of inhalation into the lungs, from which it passes into the blood, where it multiplies itself, and is thence carried to every tissue and organ of the body. 5. That it seems probable that infection may be carried by the poison adhering to the clothes of persons in attendance on the diseased cattle. 6. That the liability of sheep to take *rinderpest*, or to carry infection, is being submitted to testing in the city, which may be regarded as decisive. 7. That, even during unsuspected incubation, infected animals may communicate the disease to others. 8. That the period of incubation generally lasts from six or seven, but may extend to ten or fourteen, or even twenty-one days. 9. That there is a great risk under present circumstances in bringing together droves of cattle, as at fairs or markets, as animals may communicate infection which yet show no outward symptoms of the disease. 10. That fairs and markets for the sale of lean or store cattle ought to be for the present suspended, and the greatest caution should be exercised in regulating the traffic in fat cattle; and where markets for fat cattle are unavoidable, they should be held twice a week, so that the cattle purchased by butchers may be slaughtered without delay. 11. The committee are decidedly of opinion that cases of *rinderpest* may and ought to be treated with a view to cure; that the disease, if seen in its earlier stages, is amenable to treatment, and that even where the symptoms have become serious, the case is not to be looked upon as hopeless or its treatment abandoned. 12. That the disease may be expected to become milder in its type and more tractable after it had lasted some time, and the proportion of deaths will become notably diminished. 13. That the committee deprecate and strongly protest against the indiscriminate slaughter recommended, and to a large extent acted upon throughout the country. 14. That it is of the greatest importance that persons attending on cattle should be conversant with the earliest symptoms of the disease, and be on the look-out to detect it. The report proceeds to specify the symptoms and pathological conditions of the diseased animals; and, remarking that *rinderpest* is a disease of low type, and the tendency to death is by exhaustion, states that violent and lowering treatment is wholly inadmissible. The report offers the following as a safe and simple mode of treatment, which has led to recoveries under their own

eyes, and which seems worthy of a fair and extensive trial:—

"15. The animal should, as soon as the disease is detected, be separated from other cattle and placed in a comfortable outhouse, byre, loose-box, or stable, well ventilated but not cold. If wooden sheds be used, they should be so constructed as to admit of being easily kept warm—say at a temperature of about 70 degrees. The greatest attention must of course, be paid to cleanliness. The manure should be frequently removed, and all of it submitted to the action of disinfectants, of which the best is the cholride of lime (bleaching powder).

"16. It is of great importance to promote the circulation of the skin, and to restore the natural heat of the surface. For this purpose the animal should be carefully and vigorously rubbed down, and then covered with a warm rug. Warm drinks of gruel, bran-tea, or hay-tea, should be copiously administered, and these should constitute the only food of the animal in the early stage. The animal which is generally thirsty, may be allowed as much cold water as it wishes. Stimulant diaphoretics and diuretics will also be found useful as tending to promote the action of the skin and kidneys, and thus to relieve internal congestion, and to aid in eliminating the poison of the disease from the system. Mr. Smart's formula is two ounces of the *aqua acetatis ammoniæ* (Mindererus's spirit), with one ounce of sweet spirits of nitre, and with this he combines as a stimulant six drachms of the carbonate of ammonia in nine ounces of water. This may be given three times in the day.

"17. The loaded state of the ailmentary canal, which is a constant an occurrence in *rinderpest*, requires to be relieved by the use of mild laxative medicines, given very early in the disease. But strong saline and drastic purgatives must on no account be used, as their action would not only exhaust the animal's strength, but would prove most injurious by the irritation it would occasion to the mucous lining of the intestines in its highly congested and tender state. Professor Dick prefers as a laxative linseed oil in doses of 16 ounces, to which he adds half a mutchkin of whisky. Dr. Smart recommends a laxative consisting of two ounces of sulphur, one ounce of nitre, one ounce of powdered ginger, and one pound of treacle, with water to make a quart. Whichever of these laxatives be given, it must be repeated at intervals of some hours till a full effect has been produced. In some cases scouring (diarrhœa) proves a troublesome symptom, for the relief of which Professor Dick recommends the use of lime water in doses of a quart, to which he adds from half an ounce to an ounce of laudanum, and this he gives three times a day till the diarrhœa has been subdued. The use of stimulants should follow upon these remedies, or, if need be, they may be given simultaneously with them. The carbonate of ammonia is that which seems to act most beneficially, and of this may be given in six drachm doses three times a day.

"18. To promote convalescence tonics are prescribed. These may consist of either sulphate of iron in half-ounce doses given twice a day, as recommenced by Professor Dick, or of powder of cinchona in doses of one ounce and a half, given once a day, as recommended by Dr. Smart."

The commitee add they "entertain no prejudice for or against any particular system of treatment; they desire scientific information. They do not believe in any specific for the cure of *rinderpest*. They believe that in this as in all other diseases, sound pathological knowledge of the disease constitutes the only reliable basis for safe or successful treatment. They believe further that the treatment they have recommended can only prove successful if all the items be carefully and faithfully carried out in practice, whether it regards diet, regimen, tending, or medicine."

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the Naval Medical Compassionate Fund, held at the Admiralty on October 10, Dr. J. W. Johnston, Inspector-General, in the chair, the sum of 85*l.* was distributed among the various claimants. During the last five years upwards of 1,400*l.* has been awarded to the necessitous families of deceased members.

TEACHING OF ANATOMY AND ZOOLOGY.

CAMBRIDGE, OCT. 21.—At a meeting of members of the Senate in the Arts School this day, the report of Syndicate upon the teaching of anatomy and zoology in the University came under discussion. This report, issued at the end of last Term, states that an extension of the teaching in these subjects is necessary when regard is had to Medical students, candidates for honours in natural science, and those who wish to pass the examination in zoology for the ordinary B.A. degree, and recommends, in addition to the Professorship of Anatomy, the appointment of a Demonstrator with a stipend of 100*l.* a year, and the establishment of a new Professorship of Zoology and Comparative Anatomy with a stipend of 300*l.* a year.

Dr. Paget sympathised with the object of the report, but thought it would fail to put matters on a good permanent footing for want of a regulation such as had been introduced at Oxford—viz., one debarring the Professor of Anatomy from the practice of Medicine or Surgery. The University had a right to expect that the professor of so large a subject should not only lecture, but enlarge the boundaries of science by his own researches, or at least should have time at his disposal for so doing. The Professor could not do this while carrying on a Medical practice, the duties of which were often most urgent and the emoluments dependent upon exertion, and therefore the Professorship with a fixed stipend would probably become subordinate to the practice, and Cambridge would fall below the position of Oxford, where the zeal and activity of Professor Rolleston was a proof of the wisdom of their arrangement. In London and Edinburgh the lectureships were mostly held by young men, who resigned them when they got into large practice. Such a restriction would require an addition to the stipend sufficient, with the fees, to raise it to 600*l.* a year, while 300*l.* a year would, perhaps, suffice for the Professorship of Zoology, as it would be less likely to come into competition with a Medical practice. As to the mode of appointment, the electoral roll was an unsatisfactory body of electors to scientific professorships, and he thought the University should go to the Privy Council for an alteration of the statute in this respect.

Dr. HUMPHRY said that if the staff were not increased it would be better not to attempt to teach human anatomy here. The University was, however, pledged by the institution of new examinations to put matters on a better footing, and the funds would now bear the additional drain. The fees for degrees, though fluctuating, were a most healthy source of income, which would be likely to increase as more care was taken with teaching. Let the University give its greatest rewards for mathematics and classics, but not neglect biology, not only on account of the value of that science itself, but its importance to the public. The influence of the University on the Medical Profession was great, and it could not confer a greater boon on the public than by promoting the study of Medical or collateral sciences in its body. With regard to the restriction proposed by Dr. Paget, it might be a drawback if the Professor of Anatomy were occupied in any other way; but those who studied anatomy were a limited class, and almost all poor, so that unless the chair were highly endowed the Professor must have some other means of obtaining an income. At Oxford the stipend was 1,000*l.* a year. He (Dr. Humphry), however, did not feel the restriction as absolutely essential. Great advances in anatomy and physiology have been made by practising men, such as Harvey, Hunter, Sir Astley Cooper, and Dr. Beale. Anatomy, being a practical science, was most impressively taught to those who were going to practise it when the teacher could draw from the experience of his own life, and he did not think, taking men as they were, that the professorship would really become subordinate to a medical practice.

The Vice-Chancellor closed the debate, stating that he had been induced to recommend this measure to the Senate as the best that could be devised when regard was had as well to the lectures which were needed as to the funds which were at their disposal.

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 25, 1865.

SYPHILISATION.

At the meeting of the Harveian Society, on Thursday evening last, which was the first occasion on which the Society met for the season, it was expected that Professor Boeck, of Christiania, would make some remarks upon the subject of syphilisation, of which proceeding he is one of the most strenuous advocates. In consequence, however, of having a severe cold, the Professor was unable to attend the meeting, but nevertheless, the subject of syphilisation was partially discussed with a view of collecting information, and of being prepared with some preliminary knowledge of the merits of the practice, before the anticipated statement of the Professor himself, to be made when he recovers from his indisposition.

If the practice of syphilisation were now introduced for the first time, and if no published accounts had been presented to the notice of the Profession, it might justly be thought that any observations on the part of ourselves, or of our contemporaries, would at present be premature; but the doctrines and the practice on which syphilisation is founded have now been some fourteen or sixteen years before the world, and we consider that it falls legitimately within our province to make our readers acquainted with the outlines of the new system, and to offer some remarks on its asserted efficacy, either as a preventive or a remedial agent. But as the merits of syphilisation are still under discussion, and as the experiments in connexion with its remedial powers are at present in progress, our remarks are by no means intended either to condemn or to advocate the proceeding, but merely to serve as a guide to those who may be hitherto unacquainted with the reasons which have induced some ingenious and learned surgeons to propose an operation which at first sight appears repulsive to our feelings, and even inconsistent with our notions of pathology.

We think it right to mention in the first place, that Dr. Boeck, who is now on a visit to this country for the express purpose of conducting experiments on syphilisation, under the sanction of our Government, is not the inventor of the new system, although he is one of its most enthusiastic advocates; and we should moreover state that he is a gentleman of distinguished learning, that he is an eminent and veteran member of our own Profession, and that his visit to England is quite unconnected with any prospect of pecuniary gain to himself, and is indeed defrayed at his own cost.

The idea of curing or preventing syphilis by the practice of repeated inoculation on the same person, with the virus of chancres, originated several years ago with a young French physician, Auzias-Turenne, who laid the results of his experiments before the Academy of Medicine of Paris, by which body his doctrines were at once rejected on the score of their immorality. The next investigator in the same field was Sperino, of Turin, who was connected with the venereal hospital of that city, and whose experiments on fifty-two prostitutes, proved to himself the value of the proposed operation. Some years afterwards the new practice reached Christiania, and it formed the subject of a work, written by Dr. J. L. Bidenkap, and published in 1863, and now Professor Boeck is engaged in explaining the nature of his own researches, and of those of his Medical fellow-countrymen, to the inhabitants of our own islands.

The practice of syphilisation consists in repeatedly inoculating the chancrous matter on the chest and abdomen, and afterwards into the skin of the arms and legs, and after a great number of these inoculations, namely, from two to four hundred, it is considered that the system is so thoroughly saturated with the poison, that the point is reached when no further inoculation is possible. The whole process occupies from three to six months, six inoculations being made every three days, and the operations being repeated by taking the matter from the last successful chancres, and going on as long as the inoculations succeed.

Such being an outline of the operation itself, it may now be asked what advantages are expected to follow from its performance? The answer made by its advocates is that it is both prophylactic and curative, that it guards the system from contracting the disease, and that it cures the disease when the patient is suffering from it. But the preventive view of the question is so disgusting, and is so abhorrent to all feelings of morality, at least so far as the inhabitants of our own islands are concerned, that it may be safely withdrawn from consideration, and we can regard the operation only as a supposed remedial measure in the case of patients who already have venereal sores, or are suffering from secondary or tertiary symptoms. In such cases it is said that repeated inoculations with the syphilitic matter are followed by the cure of the complaint.

As we have before stated, it is no part of our present purpose to offer any decided judgment on the merits of this practice, and if it should hereafter be found that the results are successful, we shall readily acknowledge the fact, and admit that our misgivings are founded on erroneous data. But we cannot help throwing out the following observations upon the pathology of syphilis, with a view of eliciting information as to the theory on which the advocates of syphilisation support their views.

It is now pretty well established, though not we think universally, that there are two kinds of syphilitic sore which, although both arising from the same exciting cause, are very different in their origin and in their results and require very different treatment. There are the hard and the soft chancre, the former being the true Hunterian sore, which affects the constitution with secondary and tertiary symptoms, and the latter a local ulcer not followed by constitutional contamination. The indurated sore with its train of disastrous consequences both local and constitutional, has been hitherto treated, sometimes successfully

and sometimes not, with mercury and iodine; while the soft sore is actually made worse by the administration of mercury, and is best treated by local escharotics and constitutional tonics. But while the soft sore is inclined to enlarge, and while its matter can be readily inoculated on any other part of the body than that where it originally appeared, it has no tendency to produce any other than local symptoms. The hard sore, on the other hand, cannot be transplanted by inoculation to another part of the body, and it has a tendency to affect the constitution in the various maladies known under the names of secondary and tertiary syphilis.

Now, syphilisation in all probability consists merely in the inoculation of the matter of a soft chancre which, it is well known, may be made to produce an enormous number of ulcerations like itself, and in process of time the system will perhaps become saturated to such an extent that no further inoculation can be successfully performed. But if the original ulcer had been left to itself no constitutional effects would have ensued, and therefore it is difficult to understand how the multiplication of soft chancres over the trunk and limbs can be in any way beneficial. It is still more difficult to comprehend how the inoculation of the matter of a soft chancre can cure the constitutional effects produced by a hard one, and as to inoculation from the hard chancre itself, the results have always been negative.

But after these preliminary observations we leave the further discussion of the subject until Professor Boeck has had an opportunity of personally explaining his views, and of answering the questions which will be addressed to him. The results of the experiments now being conducted at the Lock Hospital and elsewhere will also assist very materially in the formation of a mature judgment of the merits of syphilisation.

SUMMARY OF THE WEEK.

THE CATTLE-PLAGUE.

While the community in general is justly alarmed at the continued ravages of the disease in cattle, and while sensation-writers and popularity hunters are endeavouring to gain a transient notoriety by the publication in the journals of pretended specifics or of plausible theories, some intelligent and industrious members of our Profession are making practical inquiries as to the pathology of the disease which is now decimating our flocks and herds, and depriving thousands of the population of a due supply of one of the chief necesaaries of life. At the last meeting of the Pathological Society of London, specimens were exhibited of the intestines of animals which had died of the prevailing epizootic, showing that the opinions hitherto entertained as to the anatomical character of the disease were incorrect, and that typhoid fever was not the cattle-disease, at least if typhoid fever was defined as a fever characterised by inflammation and ulceration of Peyer's glands. In the morbid specimens exhibited, in fact, these glands, so far from being diseased, were hardly visible at all, and their thickening and enlargement, which was at one time supposed to indicate an unhealthy condition, is found to be a common and probably normal condition in healthy cattle. The opinion, therefore, that the cattle disease is the same as typhoid fever must, we think, be abandoned. We are confirmed in the view we expressed some weeks ago, that the disease more resembles an epidemic influenza, of a very fatal and probably contagious character. While the London Commission is engaged in investigating this important subject, we beg to direct attention to a report, published at p. 294 of the present number, from a Medical Committee appointed at Edinburgh. This report contains some very useful suggestions, and we would allude particularly to that part of it which condemns the indiscriminate slaughter of the animals, and recommends that remedial measures should at least have a fair trial.

MEDICAL FEES.

The subject of Medical fees is naturally one which at all times engages the attention of the Profession, but particularly so at the present time, when the overstocked state of our fraternity, and the difficulty experienced by many in obtaining a livelihood, causes some of our body to overstep the limits of discretion by charging their patients too much, and others to rush into the opposite extreme of charging too little, and of thus bringing Medical services into contempt. In a communication which appears to-day in our pages, signed "Medicus et Chirurgus," and which is from the pen of a most highly esteemed and respected practitioner in the west of Scotland, the inconvenience and the injustice occasioned by the last-named error are very temperately but clearly explained. It might perhaps be scarcely believed that Medical men could be found who would go out to attend patients at the charge of sixpence! a visit, and yet we are informed that such is the case. We hope that the exposure of such conduct, which is wholly indefensible on any score of public expediency, will act as a salutary warning to the offender or offenders, and that their abandonment of their present scale of charges will obviate the necessity of publishing their names, a step which will become inevitable if the present system be continued.

The Paris Faculty of Medicine.—M. Denonvilliers, formerly Professor of Surgical Pathology, has been transferred to the Chair of Operative Surgery vacated by M. Malgaigne on the score of ill-health. The Chair of Surgical Pathology has not as yet been filled up.

International Medical Congress.—At the rising of the French Medical Congress just over at Bordeaux, it was determined to hold the next at Strasbourg, and also to use every endeavour to organise an International Medical Congress to be held in Paris in 1867, the year of the forthcoming International Exhibition.

Medical Students.—From a return just made for the information of the Inspector of Anatomy, it appears that there are no less than 1,014 gentlemen pursuing their Professional studies at the eleven metropolitan hospitals, exclusive of those studying for the Dental Profession; of the former number 321 have commenced this session. The number of students at the different hospitals varies very much; one school has a class of 249, whereas another has only 30, the number of new entries at the former amounting to 80, and at the latter to 9 only. It is stated that about 20 students are pursuing their studies for the diploma of Dental surgeon.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, OCTOBER 17.

DR. PEACOCK, President.

THE PRESIDENT, on taking the chair, said he could not express a better wish for the Society than that the Session which was about to commence might prove equally successful with those which had preceded it. He thought the long list of specimens for exhibition on that occasion afforded every prospect that it would prove so. The Transactions had not been distributed to the members, but some copies had been laid before Council, and he felt satisfied, by the very cursory observation which he had been able to make of this volume, that it would be found fully equal to its predecessors, and evinced equal ability and care on the part of the secretaries who prepared it. While in Germany, during the autumn, he had heard very gratifying testimony to the value attached to the Transactions in that country from Professor Virchow, of Berlin. He then drew the attention of the members of the Society to the rules at the back of the card, and especially to the first and second rules, which render it obligatory that notice of specimens to be exhibited should be given to the secretary before the day of meeting, and that the reports of communications should be sent in immediately after they have been made.

The PRESIDENT then exhibited a specimen of

MALFORMATION OF THE HEART.

which occurred in the practice of Mr. Roper, of Islington, in a boy seven years of age, who had always been cyanotic and liable to syncopic attacks, and who died suddenly. The specimen was an example of the most common form of malformation, in which the orifice of the pulmonary artery is contracted, and the septum of the ventricles deficient; but it was remarkable for the degree to which the orifice of the aorta was displaced, the vessel arising entirely from the right ventricle, through the circumstance that the foramen ovale was entirely closed. The vessels had been cut off too near the heart to show the ductus arteriosus, so that the condition of the duct could not be ascertained.

Mr. SHAW then brought forward the case of a patient who was the subject of

CONGENITAL DISLOCATION AT THE HIP-JOINTS.

The patient was also in attendance in the waiting-room. She was a healthy girl ten years of age. Her mother said that the delivery had been natural, and the child was never known to have been affected until she was put on her feet. It was only two years that disease of both hips had been suspected, and but one year that dislocation had been diagnosed. The position of the bones was nearly the same as in dislocation on the dorsum ilii from violence, but the elevation was greater, and the bones were placed considerably backwards. There was considerable sinking in of the loins and projection backwards of the hips.

Mr. SPENCER WELLS exhibited two

FIBROUS TUMOURS OF THE ROUND LIGAMENT OF THE UTERUS.

One of them he removed more than a year ago from a lady nearly forty years of age. It was the size of a large orange; simply fibrous in structure. Having been covered by a thick layer of fat, great doubt had been expressed by various Surgeons as to its nature. One had ordered a truss, believing it to be an irreducible hernia; some thought it malignant, others glandular, and strong opinions were given that it could not be removed without opening the peritoneal cavity. But as it was painless, freely movable, had been of very slow growth, and the neighbouring parts and glands were healthy, he (Mr. Wells) removed it, and had no difficulty in doing so without exposing the peritoneum. It occupied the right inguinal canal, and was simply an excessive growth of the fibrous tissue of the round ligament. The patient had remained perfectly well. The second tumour was much larger than the first, being about the size and shape of a small cocoa-nut. The patient was nearly fifty years of age. In every respect it resembled the other tumours, it had been easily removed and the patient quickly recovered. Mr. Wells said that he brought these specimens before the Society because he had not been able to find any description of such tumours in any Surgical work which he had been able to consult. He had been told that Scarpa had described them; but on referring to his "Opuscoli di Chirurgia" he could only find a description of the much more common condition known as hydrocele of the round ligament. He had not seen any other examples himself; but if attention were directed to the subject other Surgeons possibly might show that it was not a very rare form of disease.

TWO TUMOURS REMOVED FROM THE LARYNX IN A CASE OF APHONIA OF SIX YEARS, FOLLOWED BY IMMEDIATE SPEECH.

The patient was a single lady, of thirty-eight, who had had a bad throat for six years, the voice being reduced to a croupy whisper. During the first three years she had coughed up pieces of "flesh," one of which was an inch long and the shape of a shrimp. For the greater part of the time she could not lie down at night, from supposed cardiac disease with dyspnœa, and her complexion was very florid. On examination with the laryngoscope in April last, a long, fleshy, somewhat bulbous growth was seen to occupy the greater part of the sub-glottic space, springing from the anterior part of the larynx, below the origin of the true vocal cords, and quite immovable. The larynx in other respects was comparatively healthy, but there was much irritability and spasm of its proper muscles. After six weeks' preparation, Dr. Gibb snared a growth in the loop of wire of his laryngeal écraseur, cut its pedicle, and withdrew it firmly held by a piece of uncut mucous membrane in the retracted loop, in a similar manner to the outer coat of the artery after ligature. He now found a second and larger growth, which had formed the bed of that already removed, and this was snared six days later in a similar manner to the first, the tumour being likewise withdrawn in the retracted wire loop of the écraseur. The voice was immediately restored, for the mechanical obstruction was got rid of. In a few days the little wound cicatrised, no obstruction was visible, the trachea was normal, and the patient left for the North—cured. The composition of the tumours was wholly epithelial cells, and to the naked eye resembled a congeries of small cysts; they were of the size of small beans. The tumours were exhibited with the wires attached to the mucous membrane, and Dr. Gibb remarked that when the loop of the wire was not violently or spasmodically drawn home, the growths invariably were withdrawn with the instrument itself. The case made, he believed, his fifteenth or sixteenth in which he had successfully abstracted growths from the larynx by means of wire loops, and this in their entirety, not in fragments. The shape and position of the tumours in the present instance were well illustrated by a large diagram.

Dr. BEIGEL showed several

PREPARATIONS OF HEALTHY TEETH.

There were seven preparations illustrating several methods of preparation, and showing the different structures of the teeth.

Dr. MURCHISON showed specimens illustrative of the

PATHOLOGY OF THE CATTLE PLAGUE.

He brought forward these specimens chiefly in consequence of the statement recently made that the cattle plague was the pathological equivalent of the typhoid fever of man. In the course of the last autumn he had dissected twenty-seven cattle, and had found essentially the same appearance in all, the differences being those due to different stages only. Speaking generally and briefly, the disease was a catarrhal or croupal inflammation of all the mucous membranes, including even the genito-urinary. The chief point, however, on which he now wished to speak was the condition of the intestines. The mucous membrane was intensely red, and was covered with a gelatinous or puriform mucus, and in extreme cases even with actual lymph. On the condition of Peyer's patches Dr. Murchison dwelt at length, and showed specimens, for the sake of com-

parison and contrast of healthy intestines as well as of intes-ines taken from diseased cattle. He also exhibited portions f intestines from patients who had died on the tenth and wenty-sixth days of typhoid fever. Now, the appearances n these patches in the diseased animals were not like what s seen in typhoid, and, indeed, were exactly the opposite. 'eyer's patches gradually disappeared, so that on passing the nger over the mucous membrane they could not be felt, and n some cases the most careful naked eye examinations failed o detect them : whereas in the healthy animal they were ised the sixth of an inch above the general surface. In ie early stage the gland became full of puriform fluid, hich was easily squeezed out, and the escape of which used collapse of the glands. The condition of the soli-ry glands at first sight might seem to be that of enteric ver, but on examination they were found to consist of a ick external cyst, and were full of cheesy material, tally unlike that of typhoid fever of man. Moreover, is condition of the glands was constantly met with in althy oxen. In not one of the twenty-seven cases dis-cted had there been any submucous deposit or ulceration. he spleen and mesenteric glands were healthy, and in this spect the disease differed from both enteric fever and phus. In the fourth stomach there was seen catarrhal flammation, minute erosions, and patches of extreme ngestion or ecchymoses, and here and there sloughing of e mucous membrane. Dr. Murchison concluded by say-g that Dr. Smart, of Edinburgh, Dr. Aldis, and Mr. arge of London, had found similar apppearances in the ses they had dissected, and had arrived at the same conclu-ons. Dr. Murchison had had the assistance of several hysicians—among others of Dr. A. P. Stewart—and all reed that the disease had no relation whatever to typhoid ver.

PREPARATIONS AND SPECIMENS ILLUSTRATIVE OF THE PATHOLOGY OF THE CATTLE PLAGUE.

Dr. Crisp exhibited thirty wax preparations, as well as e morbid parts in spirits, to show the various phases of ttle plague, and to illustrate his conclusions respecting e nature of the disease. The preparations, Dr. Crisp ought all tended to show the exanthematous nature of ie affection ; among them were examples of ecchymosis of ie endocardium, and extravasation of blood under this embrane ; exanthematous spots in the cæcum and blad-r ; the congested state of the ileo-cæcal valve ; old ulcers the large intestine ; and tubercular elevations uncon-cted with disease. The conclusions were as follows :—1. at the so-called "cattle plague" or typhoid fever bears t slight resemblance, either in its symptoms or morbid pearances, to the typhus or typhoid fever of man. 2. at, looking to the symptoms and pathological changes, l especially to the rapid recovery in many cases, the lady bears a greater resemblance to some exanthematous, eases in the human subject, affecting, in ruminants efly the mucous membranes. 3. That the specific poison his disease alters the condition of the blood, and affects ecially certain parts of the nervous system, paralysing digestive organs, and thus sapping the foundations of . 4. That the disease is attended, in most cases, with a ific eruption, or exanthematous blush, affecting more or a ll the mucous membranes of the body. 5. That an al may be suffering from this disease in its first stage ut the possibility of detecting it, and in this way the se may be disseminated in our fairs and markets to a al extent. 6. That there is no sufficient proof that the of bulls, cows, oxen, and calves, in the first stage of disease, is injurious to human beings that partake of it. That the poison of the cattle plague (with the exception papular eruption on the skin) produces no injurious cts when introduced into the human system, 8. That best means of eradicating the disease is to prevent all ements of cattle and sheep for a month or six weeks ept under special circumstances), and by the establish-t of dead meat markets in all our cities and towns. Dr. P continued: I can fully confirm the statement made Dr. Murchison as to the diminished size of the aggre-glands, or crypts ; but my explanation is different to made by him. We know but little respecting the use of these glands ; but the disease appears to throw some physiological light upon the subject, for here the process of digestion is arrested, and the glands therefore were scarcely perceptible. The term "ulceration" is not warranted, I think, for ulceration seldom occurs in this disease, and when ulcers are met with they are often of old standing. The red patches are not confined to the fourth stomach ; they are even present, in many cases, in the bladder, as the preparations showed. They are probably formed first by liight effusion of serum under the cuticle, then, by the detachment of the cuticle, exposing the red membrane underneath. I have never seen the spleen or liver in an abnormal condition in this disease—another fact, as regards the former organ, that militates strongly against the typhoid nature of the affection. There is a point of great practical importance as regards the pathology of the disease—viz., the rapid disengagement of gas in many parts soon after death, or even during life, renderihg the fat over the kid-neys and under the skin "boggy" and resonant when struck with the hand, but this is not peculiar to cattle plague. I have met with it in many species of ruminants, especially in sheep that are "blown," as it is called, after gorging themselves with clover, coleworts, or other green food. As regards my conclusion respecting the innocuous nature of the cattle plague poison, I have eaten a part of the heart from which this preparation was taken, and which shows extravasation of blood under the endocardium, and I have partaken of other parts of diseased oxen. I tried these experiments upon myself before subjecting the lower animals to them. I fed a hedgehog on the worst part of the intestines of animals dying of cattle plague, and five days since the said animal brought forth four young ones, which are all doing well. I have, moreover, met with a great many men with cuts and scratches on their hands daily engaged in flaying diseased cattle, who have received no injury with the exception of a papulous eruption on the skin.

The President remarked, in reference to Dr. Murchison's communication, that it showed the condition of the aggregate glands of the intestines in the ox that had died of the cattle plague to be quite physiological, the glands being distinct in the healthy animal, and indistinct in the diseased. This corresponded with their condition in the human subject after death from diseases in which the glands were not involved. Some years ago he carefully examined these conditions in a large number of subjects who died of diseases of an acute and chronic character, exclusive of typhoid fever, typhus, &c., in which the glands are found to be diseased, and he arrived at the conclusion that the distinctness of the glands bore a direct relation to the shortness of the period which had elapsed between the actual health and the death of the individual, the glands being distinct when persons were killed or died after short periods of illness, and especially in young subjects, and very imperfectly market, when persons had been ill for longer periods, and especially in the middle-aged or aged. This corresponded also with the appearance of the mucous glands in cases of cholera. When the patient was rapidly cut off, as after six or eight hours' illnes, and especially in young persons, the glands, especially the solitary, were very distinct. On the other hand, when patients died at later periods, as after an illness of six or eight days, and especially if they were middle-aged or aged persons, the glands could often scarcely be detected.

Dr. Schulhof said that on the Continent the pathological appearances of the cattle plague were well known, and that he never heard until recently that it had been considered to be related to typhoid. As to the plan of stopping the spread of the disease by killing the diseased animals, he remarked that the plan might be useful in the Steppes, but in England it could do no good.

INFLAMMATION OF THE EPIGLOTTIS.

Dr. Crisp exhibited the tongue and larynx in wax and in spirits of a boy, eight years of age, who was indisposed for two or three days, when symptoms slightly resembling those of croup made their appearance, and he died rather suddenly. The epiglottis and parts about its base, were found red and swollen, and with this exception the organs of the body were healthy. The case occurred in the prac-

tice of Mr. Hopewell, of Chelsea, with whom Dr. Crisp examined the body.

Dr. GREENHOW then showed a specimen of

MILLSTONE-MAKERS' PHTHISIS.

The lungs were from a stone-worker, who had formerly been a French millstone-maker, and latterly a stonemason. The apices of both lungs were dense, hard, and of a coal-black colour; the bronchial tubes in the consolidated parts were dilated and rigid. The remaining portions of both lungs were denser than normal, and in parts almost black, but for the most part crepitant. Scattered here and there, in the crepitant portions of the lungs, were small, well-defined, hard nodules, 'on section' of a pale colour, which were evidently the products of chronic inflammatory exudation. In the lower lobe of the left lung there was one irregular cavity about two inches in its longest diameter, but there were no other cavities, and nothing bearing any resemblance to true tubercle. The bronchial glands were somewhat enlarged, hard, and black throughout. Some slight recent pericarditis excepted, the other organs were all healthy. Under the microscope the dense portions of black lung in the apices were seen to consist of elastic fibrous tissue, abundantly intermixed with granular exudation cells and black pigment, the latter being arranged partly in the form of small roundish nodules, partly in that of fine granules. Sections of the lungs at the junction of the condensed and crepitant portions, showed thickening of the walls of the air-cells, with a deposit of black pigment in their substance. Small portions of the dense black part of the lungs having been thoroughly incinerated, and subsequently boiled in hydrochloric acid, left a siliceous residue which, under the microscope, consisted of minute, angular-looking particles, which did not polarise light, but were dissipated on exposure to the fumes of hydrofluoric acid.

Dr. BUCHANAN exhibited

TWO SPECIMENS OF THE VOMIT OF YELLOW FEVER.

One was quite black, and had, when first vomited, presented the appearance of grains of black matter suspended in a fluid which itself had little or no colour. Microscopically this black vomit consisted of blood corpuscles, some unaltered, but mostly aggregated into yellow masses or else disintegrated, and of epithelium of the squamous, columnar, and spheroidal varieties. On infiltration the liquid part was nearly colourless, and gave no reaction of bile. This specimen was part of a large quantity vomited by a woman on the third day of yellow fever; she died the same night. The other specimen was vomited by her husband on the day of his death, the second or third day of his attack. It resembled beef-tea grounds, and was of scanty amount. Microscopically it had much the same elements as the other specimens, but much less blood, and a large quantity of torula. Dr. Buchanan expressed his regret that he could not show the Society any of the post-mortem appearances of yellow fever, on account of the repugnance of the people to allow any autopsy to be made. But he might add that the disease at Swansea ha been typical yellow fever of considerable fatality amongst those whom it attacked.

HARVEIAN SOCIETY.

THURSDAY, OCTOBER 19TH.

DR. GREENHOW IN THE CHAIR.

LABORDETTE'S LARYNGOSCOPE.

Dr. C. DRYSDALE exhibited an instrument recently devized by Dr. Labordette, Surgeon to the Hospital of Lisieux, Normandy, for examining the posterior part of the epiglottis and vocal cords by means of direct inspection, using only daylight, and dispensing with the frontal mirror and lamp. This instrument resembles a bivalve speculum vaginæ in all respects, except that it has a small laryngeal mirror at the usual angle at the back. Dr. Drysdale had seen Dr. Labordette use this instrument at the Pitié Hospital of Paris, lately in August, with complete success in cases where the posterior aspect of the epiglottis was much congested as well as the vocal cords. Topical applications were easily made by means of this instrument, as the tongue depressor drew back the epiglottis, and dispensed with the necessity for any great curvation of the probang used. Dr. Drysdale must observe, however, that he thought the instrument was only suited for a limited number of cases, and Dr. Labordette had claimed it as especially adapted to children's laryngeal diseases, such as croup, and he stated that he had saved two lives by the use of the instrument in this dangerous complaint.

Dr. STEWART related a

CASE OF FRACTURE OF THE UPPER CERVICAL VERTEBRÆ,

in which he had made a post-mortem examination. A man had fallen from a tree, and was picked up dead. Dr. Stewart had examined the cranium, but had discovered nothing to account for death. He therefore opened the upper part of the spinal canal, and discovered that the two upper cervical vertebræ had been fractured, and their bodies had been dislocated backwards. Hence there had been pressure on the cord, and death probably ensued from injury of the nerves supplying the heart and lungs.

Mr. DE MERIC had come in contact with similar cases. It was rare indeed that post-mortem examinations of the spinal canal were made, and hence the certificate of death was usually in such cases concussion of the brain. The popular expression "breaking the neck" was really more correct than this, and in many cases no doubt death was caused by the injury done to the medulla in the cervical region, not by the concussion of the brain.

Dr. CAMPS thought we did not know what length of time concussion of the brain would take in order to prove fatal. Hence the importance of examining the spinal cord in such cases.

DISCUSSION ON SYPHILISATION.

The PRESIDENT observed that the Society had hoped to have had the pleasure of seeing Professor Boeck this evening; and as he thought that all present were interested in the subject of syphilisation, he hoped some gentleman present would endeavour to explain to the society what it was and in what its advantages consisted in the treatment of syphilis.

Mr. V. DE MERIC, responding to the call of several members present, said that any remarks he would offer on this subject would be very cautious. One thing he would remark was that we were all very anxious to cure our patients, and, however we may differ as to the means, we ought always to give credit to men of science, when they, like Dr. Boeck, brought forward any novel method for treating any disease. The fact was that the main prop of the doctrine of the Professor was the dislike entertained by many of the Profession to the metal mercury. Dr. Drysdale among others will do anything rather than administer the drug and treats syphilis by expectation. And Dr. Boeck goes further and takes an heroic remedy. But both the expectant advocates and the others must prove—1. That they cure bad cases by their method, and 2. that they cure the disease in a shorter time than the givers of mercury. But on reading over Dr. Boeck's work, he (Dr. de Meric) found that the time required for treatment was three or four months, and, although he could not recollect the figures, he was convinced that if a fair comparison was made between this method and the mercurial treatment, the time of treatment would be found pretty much the same. Relapses take place too, whether you give mercury or not, and it is confessed that this is the case. Consequently on the whole he much preferred the expectant method of treatment to syphilisation, since it had the merit of not doing any harm at least. It must be remarked that after observing this disease for many years, at least twenty-two years, he was quite content with the treatment by mercury, although he did not much cry it up. Still, as the practice of syphilisation was painful, nay he might almost say barbarous, we should expect from it some very wonderful results to compensate for this and overcome the repugnance we naturally felt for it. With regard to the theory and practice of syphilisation—If an individual who is vaccinated is no longer capable of taking small-pox, we may say that he is vaccinized: but the advocates of syphilisation start from an erroneous tenet and ignore the difference

›etween the infecting and non-infecting sore. All the patients acted on are already syphilised, and hence the multiplicity of new sores has nothing to do with the matter. Dr. Boeck says the time comes when the patient becomes saturated. But then another series is commenced until, not the patient but the operator gets tired and then he is declared saturated. But he has only one syphilis all the time and as the operation takes a long time, it gives opportunity for the roseola and mucous tubercles, &c., to disappear, as it is known that they frequently will, spontaneously. The Professor had certainly brought forward all that he advanced most correctly. With respect to the advantage of introducing fresh matter in old tertiary cases, his plan had been long ago made use of by a French surgeon; and no doubt by animating the hopes of the patient it might do good in some cases. Besides which Dr. Boeck gave iodide of potassium often in tertiary cases. Broussais and Rasori, men of great genius, had had their crotchets and thus he could quite imagine how it was that Professor Boeck, a man of the highest scientific reputation, should be enthusiastic in this matter; but he could not help thinking that this crotchet was going rather to far.

Dr. SEMPLE had read Dr. Boeck's remarks in the journals, and he thought that, on his own showing, the results were unsatisfactory. The origin of the disease would prove this, since there were, he believed, two kinds of sores, the hard and the soft, the former of which was not benefited by mercury; but, on the contrary, when the metal was used, phagedæna sometimes arose. If, then, it were admitted that there were two kinds of sores, the soft and the constitutional, what good could we *à priori* expect from syphilisation, since the one disease has nothing to do with the other, and all that we could expect inoculation with the soft chancre to produce would be a series of sores, which would prove of no service in preventing injury from the hard chancre.

Dr. CHARLES DRYSDALE remarked that Mr. De Meric had placed the question in so clear a light that no one present could fail to understand how the debate on the treatment of syphilis stood at present. It was doubtless from the extreme dislike that many of the most eminent men in the Profession felt for the long-continued dosing with what Professor Fergusson lately denominated "a month's slow poisoning by mercury" that plans like that Professor Boeck had been brought forward, in order if possible to do away with such a breach of Medical doctrines that it should be necessary to administer a poisonous metal for six months to a patient because he was ill already. Whatever analogy syphilisation might have to rely on, hardened worshippers of mercury need not boast of analogy in the case of their so-called specific. He was glad to hear Mr. De Meric confess that relapses took place after mercury, and speak so humbly as to its virtues. M. Diday, too, another convert, had lately told the Profession of insanity, dyspepsia, &c., produced by the courses of mercury so fashionable in Paris a little time ago. Although he agreed with Mr. De Meric in preferring the expectant method to syphilisation, he could not return the compliment, for he thought syphilisation, as practised by Boeck, much less dangerous than the mercurial pill or bath. And as to statistics, he was a little tired of repeating them over and over again, but he would just say, that if they were appealed to the mercurialists had no case, since the disease was both simpler and required far less time when treated either by expectation or by syphilisation than by the metal. (*Vide* former debate in this Society.) As to the practice of the high-respected and most eminent Professor Boeck, he believed it was based upon an analogy which that gentleman maintained there existed between syphilis and the exanthemata, a subject which Mr. Hutchinson had recently thrown much light upon in the Hunterian Society. It was taken for granted by Boeck and many others of the London school that there was but one sore, and that the occurrence or not of secondary symptoms depended on the constitution of the recipient. In vaccination it was found that one pustule was not sufficient to saturate the body in many instances, and Professor Boeck's theory was, that the period of the exanthem of syphilis being so much longer than that of its analogue vaccination, it required a much longer period to saturate the system, and thus cure the disease, than in the former. As to his own opinion on the matter, Dr. Drysdale would only say that hitherto he had been inclined to look upon this practice as "un moyen d'expectation," to use the expression of M. Hardy; but he had watched with great interest the proceedings of the eminent and philanthropic man who was at present so zealous in its advocacy.

Mr. J. Z. LAURENCE thought that the diseases which presented the greatest analogies were syphilis, cancer, and pyæmia; syphilis and pyæmia differed only in their mode of origin and the length of time required to run through their phases. There was, he contended, no analogy between syphilis and vaccination. He must say that if we were allowed to use our common sense, there did seem something very abhorrent to the feelings in Professor Boeck's practice.

A VISITOR showed that, according to Boeck's theory, there was only one chancre. He himself had seen five men infected with hard sore by the same woman, who had a hard sore, and within forty days there appeared roseola, &c. The hard sore will not re-inoculate on the same patient.

The PRESIDENT thought it due to Professor Boeck to remark that that gentleman had come over to this country at his own expense to give the English Medical public an opportunity of observing his practice, and that he should suggest that the Council of the Society should invite Mr. Boeck to come soon to the Society, and give them the benefit of his observations.

Dr. SIEVEKING said that the Society should, he thought, endeavour to persuade Dr. Boeck to come before them at an early date. This eminent man, older and with more experience than many of the Medical men in this country, had come over entirely for the sake of clearing up a scientific point, and he thought it was best to hear all he had to say. For his own part, on first hearing of syphilisation, he could not see of what use it could be. Now, however, he had no longer any opinion on the matter, but waited to hear what was to be said in its favour by so eminent and great a physician as Boeck.

Dr. CAMPS also concurred in the advisability of the Council entreating an early visit from the Professor, since it was impossible for anyone to represent his ideas correctly. He thought inoculation for small-pox a better analogy than vaccination in the case of syphilisation.

Mr. DE MERIC agreed that it was almost unfair to broach the subject in the absence of the Professor, but his works were before the Profession, and thus public property. He was glad to hear that the experiments at the Lock Hospital were under the supervision of the Royal Commission; and, as Mr. Lane was taking great care in recording the results, the Profession was certain soon to have a most accurate historical picture of the treatment employed. These were very delicate questions as to whether certain trials ought to be made, and not long ago the Middlesex Medical staff had been censured for allowing experiments to be made on cancer. For his own (Mr. De Meric's) part, he had performed many inoculations, and he would suggest that the experiment should be made by the Professor of inoculating on some part of the head—*e.g.*, behind the ear, in order to find whether what M. Ricord had remarked held good—viz., that all chancres on the head are hard. Phagedæna very rarely takes place in cases of syphilisation, probably because of the counter-irritation of the other sores.

CAMBRIDGE UNIVERSITY.—C. W. T. Overend, from the Liverpool Institute, has just been elected to a Natural Science scholarship, of the value of 40*l.* per annum, at Sidney College. Examinations for Natural Science and other scholarships at this college take place annually in October. They are open to all students who have not entered at the University. There are also similar scholarships at Downing College. Information respecting them may be obtained from the tutors of the respective colleges.

GENERAL CORRESPONDENCE.

MEDICAL FEES.

To the Editor of the Medical Circular.

SIR,—The subject of Medical fees is at the present time apparently engrossing the attention of the Profession. This being the case, we would respectfully call your attention to the grievance of "under-charging," which, in certain districts, especially in the West of Scotland, prevails to an almost alarming extent. We lay the subject before you in the hope that you may suggest some remedy whereby the malpractice may be arrested. We are sure you will agree with us in saying that nothing so much tends to lower the status of our calling; besides it acts most powerfully as a source of discouragment to our junior members, and as a material drawback to most of the senior brethren in our Profession. We address you, Sir, with very disinterested motives, and we feel sure the large majority of our Professional brethren in this district will approve our opening up the subject for investigation, the evil lying only at the door of a very small minority.

We fear you will scarcely credit us when we say that we can produce authentic cases of a registered Glasgow Licentiate charging parties at the rate of sixpence a visit who were not only able, but willing, to pay a fair remuneration for his trouble. This, Sir, is a daily occurrence in a town not much over twenty miles south of Ayr. In this town the services of a surgeon, ripe in years and experience, may be procured for a paltry sixpence—nay more, we can instance a case in which this same practitioner travelled fully half a mile and extracted a grinder from a gentleman, for which he charged his modest sixpence. He premised his visit with a note stating when he should call, all inclusive in his handsome fee. To the credit of his patient be it said, he gave him a more adequate remuneration. Only imagine, Mr. Editor, a duly-qualified surgeon so ignoring the dignity of his Profession as to make such a charge for such an operation, and under such circumstances. We are further credibly informed that this same practitioner is ready at any time (from 12 a.m. to 12 p.m. and *vice versâ*) to drive to a village at least eight miles distant, and play the part of accoucheur for three, or at most four, half-crowns. Ten shillings, we are told, is his highest fee; so, after deducting at the rate of one shilling per mile for his travelling expenses, it leaves a very handsome moiety indeed for his time and anxiety. We could add many like instances, but think it quite unnecessary; suffice to say, matters cannot be much worse than they are at present in this district. A surgeon (now deceased) in a neighbouring village used to remark that parties coming into his parish from this district invariably grudged his Medical fees; while those coming from a town equi-distant paid his fees without a scruple. The cause was obvious. On the one hand, they had been treated to an almost gratuitous attendance; while, on the other, they had always paid their doctor a fair remuneration.

We have exposed so far this grievance, and now leave the subject entirely in your hands, venturing to hope that a little friendly counsel from you, generally directed and personally received, may aid in bringing matters a certain way up to where we should wish to see them. In the district from which you are addressed, the fault lies at the door of a single surgeon. We only wonder that any member of an enlightened body would so far pursue a course which can only tend to degrade the Profession to which he unfortunately belongs. We admit that a practitioner of the class described may be able to gain a fair subsistence while the vigour of manhood remains, dependent, as he is bound to be, on the generosity and donations of the community; but, as old age steals upon him he will, alas! in his sad experience, find that his, indeed, has been a fruitless philanthropy.

We could hear with gratification that any retired Medical man, in the absence of a regular practitioner, had given his counsel or assistance in any case of emergency; but when a Medical man in every-day practice, and in very ordinary circumstances, makes it his daily duty to attend almost gratuitously on any one who may be pleased to ask his advice, thus deliberately making generosity to the public the precedent of injustice to his Profession, we think it then full time for the brotherhood to raise the hue and cry.

The importance of the subject is the plea we urge for thus far trespassing on your valuable space.

We are, &c.,

"MEDICUS ET CHIRURGUS."

POOR-LAW MEDICAL REFORM.

To the Editor of the Medical Circular.

SIR,—I shall feel obliged by your permitting me, through the medium of your journal, again to address the Poor-law Medical Officers, as the time has arrived for me to take their opinion as to the course to be pursued in future.

Nearly ten years have elapsed since I first addressed them on the subject of the Medical relief of the poor, and, as yet, no comprehensive measure of reform has been obtained. Some of the Medical officers, in consequence of the general agitation of the question, have induced their guardians to grant an increase in their salaries, but these instances are, I fear, but exceptions to the rule, and the majority of them remain as they were, a capriciously and underpaid body of men. Some of them have fixed salaries and extra Medical fees, as the order of the Poor-law Board provides; others, have fixed salaries, and no extra Medical fees; others, fixed salaries, and some extra Medical fees; others, fixed salaries, combined with a per case payment. Some have fixed salaries, and find all medicines; others (a few only) fixed salaries, and the guardians find all the medicines, &c., &c. These various modes of payment show too clearly the entire absence of any well-digested plan of Medical relief.

In February, 1861, Parliament appointed a Select Committee on Poor Relief (England), which continued its sittings from time to time until May 31, 1864, when their Report was submitted to Parliament; but as its original proposer never intended the question of Medical relief to come before it (the inquiry was only made to embrace this subject on the motion of an independent member of the House of Commons), it will cause no surprise when I say that it was only on the last day and last hour of the session of 1861 that three Medical men were called upon to give evidence upon a question which actually involved five-ninths of the whole pauperism of England and Wales, thereby proving that the most important part of the relief of the poor was almost totally ignored; and when the Report on this question was made to Parliament, it was founded almost entirely on the evidence of Mr. Cane, a Poor-law Inspector, as is proved by the quotations contained in their Report. That evidence, I unhesitatingly say, was most inaccurate, and given in such a way as to mislead the Select Committee; but still there was a minority on that Committee who were not to be mystified by his statements, as is proved by the adjournments and amendments on this question, and a majority ultimately decided that it was requisite for the benefit of the poor that the guardians should find cod-liver oil, quinine, and other expensive medicines. But it was not until many months had elapsed, and after many importunities, that the Poor-law Board could be induced to issue a circular letter empowering the various Boards of Guardians to carry out the recommendations of the Select Committee; but as this was only a permission and not an order, many Boards of Guardians have refused to carry it out (Weymouth, for instance). Some, however, have allowed their Medical Officers to order a few articles of the druggists, others have permitted them to charge as extras for these articles. Some now find cod-liver oil, and one Board of Guardians (Southampton), have adopted the wise and judicious course of establishing a Dispensary, and now find all medicines, to the great relief of their Medical Officers and benefit to the poor. Some Boards of Guardians still, however, ignore the recommendations of the Select Committee, so far as the poor are concerned, but, in order to obtain a little peace,

ve raised the salaries of their Medical Officers ; but all is is most unsatisfactory, and it is a disgrace to a public dy like the Poor-law Board, to permit Boards of Guardians us capriciously to carry out the recommendations of the lect Committee of the House of Commons.

At the last annual meeting of the British Medical Asso- ition, held August 1, 1865, it was resolved "That a Com- ttee of this Association be appointed to inquire into the sent system of Poor-law Medical Relief, and to ascertain ether any and what alterations are required therein, order to ensure the efficient treatment of the sick poor, l the just remuneration of the Poor-law Medical icers.

"That the Committee be desired to report the result of ir labours to the next annual meeting of the British dical Association, and the report then presented contain, practicable, a complete series of proposals, which may, r adoption by the Association, be urged by it on the islature and on the Poor-law Board."

n accordance with these resolutions it will follow that measure of relief can be laid before Parliament before ruary, 1867. Are the Medical Officers willing to wait ong?

ly own impression is that a deputation should wait n the Poor-law Board before Parliament meets, and e the President to bring in a Bill on the subject of r-law Medical Relief, or make it a part of his proposed r-law Renewal Bill, failing which we should press upon liament, at its meeting in February next, the necessity Reform, which can only be done by preparing a bill laying it before them ; but this must be supported by a rly written pamphlet to each Member of Parliament, wing how the Select Committee arrived at an incorrect sion on the subject ; this must be backed up by repeated tings and private applications to members ; but all this not be done without money. Will the Poor-law Medi- Officers again make an effort and furnish it? Will each em forward to me at the least a 5s. subscription ?

is possible they may consider it would be better that ould retire from my office of chairman to the Associa- and leave it in the hands of the Committee of the ish Medical Association. If so let them send their sub- ption to Dr. Henry, 37 Great Queen street, Lincoln's- Fields, the Secretary of the British Medical Association, e will require funds if he is to act with vigour. If, on other hand, the wish is that I should continue to con- the management of this affair, as a distinct body the British Medical Association, they must send subscriptions to me, and I will take active measures ie subject.

ere never was a better time for doing so. A new ament, and perhaps ere long a new Government, may to us, particularly if the Medical Officers have all ed out to their individual members at the late elec- as was advised, the necessity of reform of the abuses existing in the system of the Medical relief of the

Can anyone have read the reports of the Lancet Sani- Commission for investigating the state of the in- ies of workhouses, without being impressed with the ity of great reform in the union houses? In the s' of Sept. 14, 1865, is a leader on this subject, and ve read :—

useful Act, moreover, was passed, empowering the lians to award pensions to superannuated officers. In ge, the officials of workhouses not uncommonly their days in the workhouse themselves, and in to avoid this fate; they frequently lingered in their when they were unable to discharge their duties. hese measures are so many improvements in the ent of that unhappy class who depend upon the for support. We may be sure that, so far from the n they impose on the country being increased by a liberal and judicious management, it will be dimi- l. Thus, as we have recently had occasion to show, it kness which constitutes the chief problem of pauper- nd a better system of Medical relief would unques- ly have the effect of diminishing the number of rs. According to the returns in the present report, the Medical relief forms but one twenty-sixth part of the total expenditure, although the able-bodied, including men, women, and children, compose even nominally but four- ninths of the whole number of paupers. The question is now, however, being thoroughly considered, and the next few years will no doubt see still more important improve- ments than those we have been reviewing."

After this statement of the 'Times,' will the Medical Officers be silent? I trust not.

The whole system of Poor-law Medical Relief requires revision. The Poor-law Inspectors, with one exception, so far as illness is concerned, are a perfectly useless set of men. They know nothing of sickness nor the requirements of the sick poor, as is proved by the monstrous state of our workhouses, as revealed by the 'Lancet' Sanitary Com- mission. There must be Medical Inspection, and that by Medical Inspectors. Dispensaries ought to be established in all densely populated places (as is the case in Ireland), and where this cannot be done, a separate payment should be made to the Medical Officer for drugs, independent of his salary. The salaries of the Medical Officers should be adjusted on a definite principle, regard being had to the number of patients and distance to be travelled, and then, and not until then, will the guardians ever trouble them- selves as to the class of persons receiving Medical relief. With a fixed salary, they are utterly regardless of the number of patients sent to the Medical Officer. In one union with which I am acquainted, a boy acts for his father, the relieving officer, and gives Medical orders to all who ask for them, and there the midwifery orders to the wives of the artisans are very numerous, and as the guar- dians do not pay any extra Medical fees, they make no inquiry. This I need not say is most unjust to the Medical Officer.

There ought to be a superannuation fund for such of the Medical Officers as are incapable of doing their work, and are in such a pecuniary position that they cannot give up their appointments ; it is a cruelty to the poor to insist on men doing that which they are physically incapable of accomplishing. There are many other points to be con- sidered, but in a letter of this kind sufficient has been said to arouse the thoughts of all men who are desirous of im- proving the Medical relief of the poor.

12 Royal terrace, Weymouth, I am, &c.,
21st October, 1865. Richard Griffin.

PARISIAN MEDICAL NEWS.

Remarks on Fibro-plastic Tissue.

A young man, aged twenty, recently discharged fromthe Artillery, was admitted last year into M. Nélaton's wards at the Hospital of the School of Medicine, for a disease of a serious nature and of frequent occurrence, of which the Professor stated that he met twelve or fifteen instances annually.

Five years ago, the patient noticed for the first time an indolent tumour of the size of a bean, situated in the lum- bar region ; it caused him no particular inconvenience, and remained in the same condition for four years. At the begining of the fifth year, however, the disease changed aspect, and the growth rapidly increased in volume. The surgeons whom the young soldier consulted, performed a crucial incision, but copious venous hæmorrhage supervened and arrested their proceedings. The wound healed, but after a short time the scar gave way and a certain amount of blood escaped. Since that period, no solid cicatrisation took place, hæmorrhage occasionally recurred, and at last the man applied for admission into hospital.

The following was his condition :—In the left lumbar region, and extending slightly over the buttock, lay a tumour fifteen lines in diameter, covered by diseased integu- ment, and ulcerated in one spot, in which was observed a clot of blood.

In its other parts the growth was of irregular and unequal consistency, and attached to the skin. The mass was partly movable, the mobility not extending beyond half an inch in every direction. No sensation of distress,

heat, or weight, was complained of, with the exception of occasional pain at a distance from the tumour, analogous to that sometimes observed in hygroma.

The mass was not, however, a hygroma; neither could it be looked on as syphilitic, nor as a sanguineous growth, an opinion erroneously entertained by the surgeons who had attempted its removal.

The case was one of fibro-plastic tumour, a kind of sarcoma which of late years has given rise to much discussion. Such tumours were at first considered as benignant, and not liable to relapse after extirpation, and not likely to become diffused over the system in the same manner as cancer. In this respect, however the opinion of surgeons is now different, and the disease is not looked on as incapable of becoming malignant.

This view, says M. Nélaton, must not however be exaggerated. The Professor conceives that the surgeon can easily discriminate the cancerous nature of a tumour without reference to histological research. He gives the name of cancer to any growth which displays a tendency to increase indefinitely, and involves the tissues with which it is in contact, which evinces an inclination to ulcerate and poison the system, relapses after extirpation either in the cicatrix or elsewhere, and always terminates fatally.

The diagnosis of this class of tumours can be fairly established without microscopic investigation pointing to the existence of peculiar cells with their nuclei, and from mere clinical observation the surgeon can easily acquire the requisite information. It must, however, be observed that amongst the many varieties of growths which, under the general denomination of cancer, invade and destroy the healthy structures of the body, some are obviously less inclined to run throvgh the course we have delineated, and amongst them we mention the fibro-plastic. In this respect, M. Nélaton opines that histological researches have proved especially useful, in making us acquainted with the kinds of cancer that justify a more favourable prognosis, and in which the presence of certain elements encourages a hope that extirpation may not be followed by a recurrence of the disease.

In conclusion, the Professor considers fibro-plastic growths as cancers, but as cancers possessed of characters of a more favourable description than all others.

Extirpation is the only applicable treatment, but a considerable amount of healthy tissues should be included in the operation. Indeed, these tumours are exceedingly apt to return in the cicatrix or in its immediate vicinity.

It is unnecessary to dwell on the operation performed in the case which suggested the present remarks. In accordance with the precept above alluded to, a large extent of healthy tissue and a portion of the fascia were removed. The wound was dressed with alcohol, and whether the suppuration was decomposed or neutralised by this liquid, or its quantity merely reduced by the application, the wound healed promptly, and almost without the appearance of any morbid secretion.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on the 12th inst.:—William Parker Hoare, Dartford, diploma of membership dated April 8, 1836; Alexander Charles McLeod, the Queen's Indian Army, November 13, 1840; James Oldham, Brighton, December 10, 1841; and Joseph Bainbridge Fife, Newcastle-on-Tyne, June 25, 1842.

APOTHECARIES' HALL.—Names of the gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, October 12, 1865:—James Mare Taylor, Hanley, Staffordshire; Moses Lyons, Birmingham; William Hixon Arrowsmith, Coleshill, Warwickshire; Sydenham John Knott, St. Mary's Hospital; Thos. James Webster, Conway, North Wales.

THE QUEEN'S UNIVERSITY IN IRELAND.—At a meeting of the University, held in Dublin Castle on Wednesday, the 11th inst., the following Medical and Surgical degrees, &c., were conferred by the Lord Chancellor of Ireland, Vice-Chancellor of the University. The prizes were presented to the successful candidates by His Excellency the Lord-Lieutenant:—*The Degree of M.D.—First Class.*—None.—*Second Class.*—Reuben Bolton, John James Charles, Isaiah De Zouch.—*Third Class.*—None.—*Unclassed.*—William Alexander, Daniel Ambrose, John Bligh, Henry John Brown, Cornelius F. Buckley, Joseph Wallace Chesnut, Henry Comerford, William Alister Catherwood, Alexander Filson, B.A., Joseph Augustine Fitzpatrick, Thomas C. Gilmore, Patrick Heas, Emerson Henry, John Sinclair Holden, Oscar D. Honiball, Ulick Albert Jennings, William B. Jonhstone, Mark Long, James Macartney, Henry J. Madden, Edward M'Crystal, Samuel D. Millar, John Henry Newman, Charles O'Hara, B.A., William John Rankin, Jas. Joseph Louis Ratton, Daniel O'Connell Raye, David S. H. Smith.

The Degree of M.CH.—John Bligh, Reuben Bolton, John James Charles, Henry Comerford, Francis Duffy, M.D., Joseph Augustin e Fitzpatrick, Richard Malcolm Graham, M.D., Patrick Heas, Emerson Henry, Oscar D. Honiball, Ulick Albert Jennings, H. M'Noughton Jones, M.D., William Henry Jones, M.D., Robert Dwyer Joyce, M.D., Patrick F. M'Gloin, M.D., Alex. Hay Hill, M'Murtry, M.D., Samuel D. Millar, Micl. O'Kennedy Morris, M.D., Thomas Ffrench Mullen, M.D., John Henry Newman, Patrick O'Keefe, M.D., Stephen O'Sullivan, M.D., Patrick John Shannon, M.D., George Sigerson, M.D.

THE CATTLE PLAGUE COMMISSION.—We learn with pleasure that the Commission have decided to cause a series of experimental investigations to be conducted on a plan very similar to that which we last week suggested as desirable in the public interest. We are satisfied that the main utility of this Commission will consist in the careful conduct of an extensive experimental investigation. We regret, however, to find that the funds placed at the disposal of the experimental committee of the Commission are utterly inadequate to the object in view. And, strange as it may seem in a matter of great national importance and involving pecuniary interests so considerable, the committee are under the necessity of appealing in a deprecatory form of request, suing almost *in formâ pauperis*, to the distinguished men whose services they wish to engage in the inquiry. This is neither dignified nor fair. We can imagine that it is a source of pain and humiliation to the Medical members of this Commission to be obliged to offer men of great eminence and large engagements a remuneration so small as to require an apology when offering it, and to necessitate an appeal to their public zeal as a supplement. This is what has been done, and we cannot conceive a more undignified position for a Government to assume under such circumstances. We suppose that the treasury of the country is not yet so low but that public services of so much importance should be fairly paid for. We understand that Dr. Bristowe has been requested to undertake a series of post-mortem inspections; Dr. Murchison to report on the pathological relations of the rinderpest to other diseases; Dr. Sanderson, with the co-operation of Professors Varnell and Pritchard of the Veterinary College, on the propagation, the symptoms, and treatment of the disease; Dr. Marcet on the chemistry of the blood and tissues, and the value of disinfectants; Dr. Lionel Beale on the microscopic appearances of the diseased organs; and Prof. Gamgee on sanitary restrictive measures. These inquiries, will, of course, involve a course of original investigation of each of the different subjects allotted. These investigations will be conducted on the premises of the Royal Veterinary College, Camden town, and are to be commenced immediately.—'Lancet.'

ROYAL COLLEGE OF SURGEONS.—A skeleton of that rare and singular animal the aye-aye, or Chiromys, has lately been added to the Hunterian Museum. It is an inhabitant of the island of Madagascar, where it was first discovered by Sonnerat about the year 1780. The specimen brought home by that traveller, and presented by him to the celebrated French naturalist, Buffon, has remained until within a few years the unique representative in Europe of this remark-

›le creature. By Cuvier, and many other zoologists, it as considered as a member of the Rodent order, on account the conformation of its teeth resembling those of the awing animals; but De Blainville, and others, laying ore stress upon the character of the limbs, placed it among e Lemurine-quadrumana, or monkey-like animal. This ew has been completely confirmed by the dissection of a ecimen recently sent to Professor Owen, by Dr. Sandith, a fully illustrated account of which will be found in the Transactions of the Zoological Society' for 1863. A living ample is now in the Regent's Park gardens, but, as it is rely nocturnal in its habits, it is rarely seen by visitors. stuffed specimen has lately been presented to the Univery of Cambridge by Mr. A. Newton. Besides those above entioned, very few examples of this rare animal have as t been received in Europe. The skeleton just added to e College Museum was discovered in the possession of a aler in objects of natural history in Paris, by Mr. Flower, e indefatigable conservator, who at once secured it at an exse of 20*l.* for the collection with which he is so deservedly nnected.

M. Velpeau on the Treatment of Cholera.—At a ent meeting of the French Academy of Sciences, M. lpeau made the following, among other remarks:—To licate efficacious remedies is easy to say, but difficult to lise. The cholera is a malady as yet really little known, l which, like other maladies, is often cured without nedies. Many maladies, gentleman, are cured without nedies. The truth should be told. In 1839 we tried all e means which are at this day again so much spoken of. some instances they were successful; in others they led. Was it because the patient cured himself alone, or s it the remedy that cured him? We do not know. w many persons are sure of their remedy? They speak it confidently, and yet the patient is lost. It is probable t in the first case he cured himself, and that the remedy not do much. This does not prevent every one from ieving that his own receipt is infallible. Every doctor, e every other mortal, has his remedy. There is nothing lificult as to indicate remedies where every one meddles the matter. M. Velpeau then related an anecdote of ais XIV. and his physician, Fagon, exemplifying what had just said, and continued:—I am obliged to avow t it is not always in our power to point out an efficaus remedy. The cholera is no doubt caused by the oduction of a poison into the organism. If the onous element is in small quantity, and the organism ng, it makes no ravages; if the contrary be the case, danger is real. Also when the patient absorbs what is inistered to him, his cure is probable. But sometimes stomach refuses to absorb anything; and in this case urse should be had to external means, which are n insufficient. In a word, the malady almost always mences by characteristic symptoms, such as premonidiarrhœa. The preventive treatment is easy, and it r each person to guard himself. Excess of every kind ld be carefully avoided, and the rules of salubrity tively observed. The means of arresting the malady s outset are very simple. My advice is this—pour three to four drops of laudanum on a lump of sugar swallow it. Repeat in two hours afterwards, and so until the cholic and vomiting pass away. Take also small injections of starch, poppy flowers with six, n, eight, or ten drops of laudanum. This treatment almost always suffice to stop the diarrhœa, and antee against the malady.

HE College Fellowship.—During the last three days xamination in Mathematics, Classics, and French, for Fellowship of the College of Surgeons, has been going The names of the successful candidates cannot be asined until next week.

. Thomas's Hospital.—The work of preparing for erection of St. Thomas's Hospital on its new site by the of the river at Stangate, is already begun.

NIVERSITY College Hospital.—Notice has been re-d of the munificent bequest of 4,000*l.* to the above institution by the late Nathaniel Soames, Esq., of Warwick gardens, Kensington.

Presentation.—The officials employed at the railway stations of Haverfordwest, Clarbeston, Johnstone, and Melford, have presented a beautiful silver inkstand to E. P. Phillips, Esq., Surgeon, for his kind and constant attendance during a late period of severe illness amongst them.

Patent Medicine Licences.—In the year ending March last, the sum of 6,125*l.* was paid to the revenue by 10,922 vendors of patent medicines.

The Warsaw Lunatic Asylum has recently been visited by the police; and of 144 patients, fifty were found to be political offenders, who had used the asylum as a place of refuge. The physicians as well as the offenders were arrested.

Sanitary State of Lincoln.—The inhabitants of Lincoln are now zealously engaged in improving the sanitary state of the city. The mortality is considerably above the average, being nearly 28 per 1,000.

Infanticide.—It was resolved at the Warwickshire Quarter Session this week, "That a memorial be presented from this court to Secretary Sir George Grey, calling attention to the great increase of infanticide and concealment of birth of children, and urging the necessity of some amendment of the law with a view to remedy the evil."

King's College, London.—The Medical Society commenced its sittings on the 12th inst., when an introductory essay was delivered by Dr. H. L. Kempthorne, on the Mutual Relationship of Students. The lecture, which was of a very entertaining as well as instructive character, was listened to with marked attention and applause by a crowded assembly, which included many old pupils of the College. The chair was taken by Mr. Francis Mason, the newly-elected President of the Society.

Bequest to a Physician.—The Duke de Gramont Caderousse, well known on the turf and in the Paris fashionable world, has left the remains of his fortune, which, though impaired by prodigality, is said to be still something considerable, to his physician, Dr. Besclot, with the exception of a legacy of 2,000*l.* to some other person.

A Nice Point of Differential Diagnosis.—M. Gibert lately stated before the Academy of Medicine of Paris that in the diarrhœa premonitory of cholera (miasmatic diarrhœa) the tongue is swollen, pale, moist, white, and covered with a layer of mucus; whilst in bilious or inflammatory diarrhœa the tongue is red, dry, small, and sharp-pointed.

Mr. R. J. Harding, who was elected on the 13th inst., at Sidney Sussex College, Cambridge, to a Senior Taylor Scholarship, is the son of Mr. Wm. Harding, Vice-President of the Medical Society of London. Mr. R. J. Harding was from University College, where he obtained the Mathematical Andrew Scholarship at the end of last session, and where he had previously been Cook Prizeman of the College School.

DEATH.

Williams.—October 21st, of scarlatina, at Killucan, Co. Westmeath, Anne Jane Georgina Sinclair, youngest child of John William Williams, A.M., M.B., F.R.C.S.I., Surgeon Westmeath Rifles, aged one year and eleven months.

APPOINTMENTS FOR THE WEEK.

Wednesday, Oct. 25.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

Thursday, Oct. 26.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Friday, Oct. 27.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, Oct. 28.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

Monday, Oct. 30.—*Operations* at St. Mark's Hospital for

Fistula and other Diseases of the Rectum, 1½ p.m, ; Metropolitan Free Hospital, 2 p.m.

TUESDAY, OCT. 31.—*Operations* at Guy's Hospital, 1½ p.m. ; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Lectures, chiefly Clinical. By T. K. Chambers, M.D. Fourth Edition. London : John Churchill and Sons.

Nice and its Climate. By E. Lee, M.D. Second Edition. London : W. J. Adams, 59 Fleet street.

Health Resorts of the South of France. By E. Lee, M.D. London : W. J. Adams.

The Elements of Prognosis in Consumption. By J. E. Pollock, M.D. London : Longman and Co.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

To SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

THE SECRETARY OF THE EPIDEMIOLOGICAL SOCIETY.—The memorial is inserted.

"MEDICUS ET CHIRURGUS."—The letter is inserted.

CANTABRIGICULIS.—The communication is received.

DR. H. S. PURDON.—The paper is inserted.

X. (Manchester).—The best remedy for the itch is sulphur in some form. The cleanest and perhaps the most expeditious plan is the use of a bath containing what is called the liver of sulphur, the *potassa sulphurata* of the British Pharmacopœia. But is our correspondent sure that the complaint is really the itch?

CHEMICUS.—The microscopical and chemical toy, known as "Pharaoh's Serpent," is caused by the slow combination of sulpho-cyanide of mercury mixed with a pastile.

A SUFFERER.—The symptoms are probably nervous, but your best course is to consult some respectable Medical man.

THE TREATMENT OF ESCHARS FROM BURNS.

To the Editor of the Medical Circular.

SIR,—Will you be kind enough to give me your advice (in your corner for answers to querists) in a case which is as follows :—A young unmarried lady applied to me lately for advice on two eschars from a burn, the one about an inch in length under the left eye, and the other about two inches in length, commencing at the angle of the mouth, extending downwards, the latter of which is considerably elevated, both caused by a fall on the fireplace while in a swoon. I have looked over a number of works on Surgery, but cannot find a word on the treatment of eschars. I will, therefore, feel obliged if you will pay attention to the above request.

I am, &c., "LAMBDA."

[Perhaps some of our readers may suggest a mode of treatment.—ED. MED. CIRCULAR.]

MR. G. K. H. PATERSON'S letter will be inserted next week.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 73 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments, forwarded for 6 stamps

Brass and Zinc Door-Plates.—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges. Chemists' Shops fitted up with Window-sill Plates in the plain or O.G. Patterns. Lists of Prices post free.

Plates altered and repaired.—Country orders punctually attended to.

36 CHANDOS STREET, CHARING CROSS, W.C.

Kamptulicon, Floor-cloth.—The attention of the Medical Profession is requested to be given to the many advantages of this article as a floor covering, for the Wards of HOSPITALS, Surgeries, Nurseries, &c. It is non-absorbent, quiet, and warm to the tread, will not hold dust, is very easily and quickly cleaned, and will stand any amount of hard wear. It has already been adopted in several hospitals.

GOUGH and BOYCE, 76 CANNON STREET WEST,
Original Patentees and Manufacturers.
Forwarded to all parts of the Country.

Treloar's Kamptulicon,
COCOA-NUT MATTING,
AND OTHER DURABLE FLOOR COVERINGS,
67 LUDGATE HILL, LONDON,
Three doors from the Railway Bridge.

Geo. Smith and Co.'s Pure Extract of CALVES' FEET for INVALIDS and CULINARY USE. Sold in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Druggists, Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland street, Regent street Office : 94 Upper Thames street, E.C.

Medical Fixtures and Glass Manufactory, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Altering in the above Profession, that he has an extensive assortment of SHOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc

H. Silverlock's Medical Label Warehouse, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctor's Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.
YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.
SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.
LABEL CASES for the use of Surgeons, 14s., 18s., and 24s.
LATIN SLIP LABELS for Wholesale Druggists.
Catalogues sent on application.

William Hawke, Wild Court, Great WILD ST., DRURY LANE, LONDON W.C., (late Ansell and Hawke), Manufacturer of every description of Shop Fittings, Dealer in Medical Glass, Earthenware, and all kinds of Shop Utensils, Medical Labelling, Writing, and Embossing on Glass.

Drawings, Specifications, and Estimates furnished for Fitting-up Druggists' Shops and Surgeries with every requisite, and for erecting Shop-fronts. Druggists' Stocks and Fixtures valued.

J. Clarke (late Thompson), Surgical Instrument Maker, Cutler, Truss and Bandage Maker, [illegible] Piccadilly, near Regent's Circus, W.

The Medical Circular.

SCIENTIFIC ARTICLES.

A SUCCESSFUL CASE OF EXCISION OF THE HEAD OF THE FEMUR FOR GUN-SHOT FRACTURE.

By George A. Mursick, M.D.,
Brevet Captain and Assistant-Surgeon U. S. Volunteers.

ugh Wright, a private of Co. G., 8th New Jersey Voluners, aged twenty-eight years, married, and of sound conitution, was admitted to the Stanton U. S. A. General ospital, Washington, D. C., May 25th, 1864, he having en wounded in the battles of the Wilderness, Va., May h, by a Minie bullet, which entered the right thigh about e inch to the inner side of the femoral vessels, and two ches below Poupart's ligament, passed backwards and wnwards, shattered the neck and trochanters of the feur, and lodged behind the bone. When admitted the illet had not been extracted. The parts about the seat fracture were much irritated by the rough handling he id received during transportation from the battle-field; herwise he was in good condition.

May 27th.—The local irritation is much diminished, but abscess has formed about the seat of fracture. *Operation.* The patient being etherised, an incision six inches in ngth was made over the trochanter major down to the ne; the fractured splinters, including both trochanters, ere then extracted; the neck of the bone was seized with forceps, and held firmly while the capsule of the joint and e ligamentum teres were divided; the head of the bone as then removed without difficulty. The upper sharp end the femur was sawn off with a chain saw. The bullet, a inie, much battered, was found lying in the abscess, beid the neck of the bone. The quantity of blood lost ring the operation was small; no ligatures were required. e exhibited a good deal of shock, and reaction was slow. e wound was carefully cleansed, dressed with dry lint, d left to heal by granulation. To keep the limb in posin, long bags, filled with sand, were laid on each side of and moderate extension made by means of a weight ached to the leg and suspended over the foot of the bed. Morphiæ sulphat., gr. j., at night.

May 28th.—Has passed a restless night, and exhibits a od deal of nervous agitation; pulse frequent and feeble; gue dry and furred in centre; has some fever. ℞ Spts. gallici, ℥j. every three hours, and Opii pulvis, gr. j. every r hours, with beaf tea ad libitum.

May 29th.—General condition much improved; pulse er and less frequent; wound discharges freely; treatit continued; wound to be dressed with a weak solution ermang. potassa.

June 1st.—Continues to improve; the wound looks well, the character of the suppuration is good. Stimulants uced to ℥iv. daily.

August 1st.—He has continued to do well. The wound filled up with granulations from the bottom, with the eption of a sinus that leads to the bone. It continues to purate quite freely, and some small pieces of dead bone e come away with the discharges. He has gained conrably in flesh, and his health and spirits are good.

Aug. 23rd.—The upper part of the thigh is swelled and ful, and the discharge from the wound has increased in ntity. Yesterday he attempted for the first time to sit in bed, but, owing to the rigidity of the parts and the lutination of the muscles, the pain caused by the sitting posture was so severe that he was soon compelled to lie down again. ℞ Cold evaporating lotions to the thigh.

Aug. 27th.—The swelling of the thigh has increased; the discharge from the wound is very free, thin, and flaky; the surrounding skin is glazed and doughy to the touch. The wound of entrance has reopened, and discharges some thin pus. An abscess has formed on the inner side of the thigh; incised it and evacuated about ℥iv. of thin and flaky pus. He is rather restless, but says he feels well. ℞ Tinct. ferri chloridi, gtts. xx. every six hours, alcoholic stimulants, and a nutritious diet.

Sept. 1st.—The swelling and inflammation of the thigh continue. He complains of nausea and want of appetite. An abscess is forming on the outer side of the thigh. ℞ Flaxseed poultice to abscess.

Sept. 5th.—Incised the abscess and evacuated a large quantity of thin flaky pus, which smells very offensive; has some irritability of stomach, which is controlled by Hoffman's anodyne.

Sept. 6th.—The edges of the incision in the abscess are sloughing. ℞ Acid. nitric, to be applied freely.

Sept. 9th,—Has diarrhœa. ℞ Bismuth. sub. nit., gr. x., Opii pulv., gr. j., every six hours.

Sept 11th.—The slough has cleaned off, the edges of the wound are covered with florid granulations; the discharge from the abscess continues free; diarrhœa continues. ℞ Acid. tannic., gr. v., Opii pulvis, gr. j., three times a day.

Sept. 13th.—The diarrhœa has nearly ceased; his general condition has improved; the wounds look well; the discharge from them continues free, and has improved in quality.

Sept. 25th.—Removed from the wound of operation a large ring-shaped exfoliation, from the upper end of the femur.

Sept. 26th.—Removed another exfoliation from the wound.

Oct. 7th.—Since the exfoliation of the necrosed bone, the swelling of the thigh has subsided; the discharge from the wounds has diminished much in quantity, is improved in quality, and presents the appearance of laudable pus; the diarrhœa has ceased; his general condition has much improved, and he is able to sit up in bed.

Oct. 30th.—A sinus from the wound of operation, and one from where the abscess was, on the outer side of the thigh; leads to the bone, a portion of which is necrosed.

On the 1st of November I left the hospital. I am indebted to Dr. Garland for the following history of the case from that time until Wright was discharged from the hospital.

Nov. 24th.—He continued to do well until this date, when the limb became inflamed and swollen. Cold applications were applied to it, and tonics and stimulants given internally. During the later part of December, another abscess formed on the outer side of the thigh, which was incised, and a quantity of unhealthy pus evacuated. The swelling and inflammation again subsided, and he continued to do well until February 6th, 1865, when another abscess formed in the lower third of the thigh on the outer side; this was incised and the pus evacuated. Several small pieces of dead bone have come away with the discharges from the wound of operation. About the middle of March, 1865, he began to get out of bed, and walk about the ward on crutches. On May 3rd, after getting out of bed, "he let his leg fall, and hurt it;" this was followed by inflammation and swelling of the thigh, and an abscess formed in the lower third of it, on the inner side; this was incised, and a small quantity of pus evacuated. He was now attacked with erysipelas, which extended from knee to the hip. This was combated with tonics and stimulants (iron, quinine, &c.), and it rapidly disappeared. From this time he did well, taking daily exercise about the hospital on crutches. On the 17th of April he left the hospital for his home in New Jersey.

July 18th, 1865.—I saw him at his home in New Jersey, and found his general condition to be as follows:—General

health excellent; the wounds and sinuses have been entirely healed since the beginning of May. The upper end of the femur is firmly attached to the pelvis by ligament, about one and a half inches long; the agglutination of the muscles and the atrophy of the limb have nearly disappeared; he exercises considerable control over the motions of it, and can flex and extend it slightly; the voluntary motions of rotation and abduction are lost; adduction is performed to a limited extent. Motion of the knee-joint is also limited, in consequence of the thickening and consolidation of the surrounding tissues, resulting from the inflammation. He states that, for the last two months, his improvement in the use of the limb has been very decided. When he first commenced to walk about, "the limb felt like a weight attached to his body." This sense of weight has now entirely disappeared. He generally walks with crutches, but can walk with the aid of a cane alone. With a high shoe and a cane, he walked in my presence a distance of over one hundred yards. It is only about two weeks since he commenced to walk without crutches. The progress he has made in that time has been very satisfactory, and he bids fair to have a very useful limb. The shortening of the limb is four and one-half inches.—'New York Medical Journal.'

THE CHOLERA.

FRANCE.

In order to give confidence to the Parisian public, the Emperor Napoleon, on Friday, 21st of October, visited the Hôtel-Dieu, and passed an hour amongst the patients suffering from cholera, speaking to them, inquiring if all their wants were supplied, and giving words of encouragement to the sufferers, and of commendation to the attendants.

The Emperor's visit has greatly increased his popularity among the Paris population. The Empress too has visited the hospitals. The 'Moniteur' gives the following account of the proceedings:—

"Her Majesty, accompanied by Viscountess Aguado, Lady of the Palace; Mademoiselle Bouvet, scarcely yet recovered from the accident at Neuchâtel; the Marquis de Lagrange, her Equerry; and M. Duperré, Orderly Officer to the Emperor, devoted the whole of yesterday to visiting the cholera patients. Notwithstanding a violent cold from which Her Majesty had been suffering for some days, forgetting her own fatigue to occupy herself with the sufferings of others, she went in succession to the Beaujon Hospital, to that of La Riboisière, and lastly, to that of St. Antoine. The Empress visited the cholera wards, and, approaching the bedside of all the patients, asked them questions and encouraged them with the solicitude and devotedness of a Sister of Charity. Her Majesty was rejoiced to find that the number of cures announced a notable amelioration in the course of the epidemic, and she repeatedly testified her satisfaction at the attention paid to the sick and convalescent, and in which all those employed showed a rivalry of zeal. On leaving each of the three hospitals the Empress was greeted by the acclamations of a numerous crowd, who testified in the warmest manner the emotion inspired by the self-devotedness of her Majesty."

The Emperor, from the funds of his privy purse, has transmitted to the Minister of the Interior the sum of 25,000f., to be distributed among the families of the victims of the cholera. To that sum the Empress has added 15,000f., and the Prince Imperial 10,000f. The 'Avenir National' publishes a "communicated" note correcting certain assertions which it had erroneously made. The rectification says:—

"You have announced that the internes of the hospitals had in vain demanded an amelioration in the dietary regulations. You are altogether misinformed, as no demand of that nature has reached the directors either of the hospitals or of public assistance. Ever since the commencement of the epidemic the authorities have taken the initiative in granting exceptional allowances to the pupils charged with the cholera wards, as also to the Sisters, and to all the attendants who are in any way brought in contact with persons attacked by the malady."

The 'Patrie' says—

"It is not impossible to put people too much on their guard against the falsehood or exaggeration of certain reports with respect to the prevailing epidemic and having access to the surest sources of information we are in a position to contradict the rumours which have been current relative to the evacuation of certain colleges and schools in Paris. Unfortunately it is too true that three pupils of the Collège St. Louis have fallen victims to cholera; but the evil has not gone further, as no other case has taken place in any of the establishments of education. That fact was ascertained when the Minister of Public Instruction paid a visit to those institutions, where all hygienic precautions are taken against the invasion of the malady."

It appears that those who have suffered most from the epidemic in Paris are the *chiffonniers*, or ragmen, and the street sweepers. On the former class it has fallen so heavily that there is some intention of suppressing the trade altogether.

A correspondent of the 'Times' writes from Nice:—When the cholera first made its appearance at Marseilles and Toulon, a large proportion of the wealthier classes fled in various directions; as the epidemic gained ground the example was followed by the workmen and artisans, who flock in numbers from every little town and village along the Reviera to the dockyards of Toulon. Crowds of them made their appearance in every train that arrived at Nice, and bivouacked in the open air on the boulevards, squares, and above all in the grand avenue of the Prince Imperial, which leads from the terminus to the Place Masséna. The result of this was that one morning all Nice was alarmed by a report that there had been several cases of Asiatic cholera. On investigation it was found that the persons who had suffered had brought the epidemic with them to Nice. The authorities at once took the promptest measures against the spread of the disease. An unlimited credit was opened by the municipality; the emigrants were met at the station by gendarmes, and there detained till they were ready to proceed to the frontier in carriages and omnibuses, provided for the purpose. In the meantime they were liberally supplied with all the necessaries of life. There was no harshness in this, as, apart from the urgent necessity of self-preservation, the emigrants, though almost exclusively from the dockyards of Toulon, La Seine, and Cassis, were most of them Piedmontese, Genoese, or workmen, from the poor and migratory populations of Ventimiglia, Oneglia, San Remo, Savona, and the Italian towns along the shore of the Mediterranean, A correspondent from St. Dalmas, a village at the foot of the Col di Tenda, writes that many hundreds had found their way over the pass. The villagers everywhere refused to receive them, but supplied them with food and wine, allowing them to bivouac 300 or 400 yards from their homes. There is no doubt that much misery and many lives were saved by the measures adopted by the Mayor of Nice. Had the fugitives not been supplied with the means of getting to the frontier, they would have wandered all over the country, outcasts from every town or village, without means for providing themselves with food or transport. As it was, they were sent on with all speed to the frontier, and their *morals* preserved by just enough discipline to prevent their flight degenerating into a panic rout. An Italian described to me the scene before the Orphan Asylum at Nice, where numbers encamped on their first appearance in the town. He went among them, and observing some of then lying on beds and mattresses, found they had brought them to Nice from their own homes. "Voila, Monsieur," exclaimed one, "le matelas sur lequel mon père est mort du choléra hier au soir." Too much stress cannot be laid upon the fact that of the nine deaths that occurred more than a fortnight since, not a single victim was an inhabitant of the town. The fact is, that Nice has been singularly healthy this summer. The average mortality is 6 5-6ths a day. During three days, when considerable alarm prevailed, the register fell as low as one per diem. The peculiar situation of the town, swept not only by the sea-breezes, but by every

ıth of air that finds its way from the mountains down broad bed of the Paillon, is singularly favourable to the ipation of miasma and epidemic poison. The alarm of lera has moreover had a most wholesome effect on the itary state of Nice. Apart from the temporary precau- s, permanent improvements have been made. A sewer been laid down the whole length of the route de France, the drains trapped and covered, where till this summer ilential streams flowed slowly along the sides of the , and formed stagnant pools of black ooze that reeked simmered under a blazing sun. The buildings in the town have been whitewashed at the public expense, police orders issued for disinfectants to be thrown down lrains of every house. It is almost impossible to get that is not too tough to eat, as the inspection of the tets is so severe that if there be but a suspicion of taint hop is immediately closed. Last week rain fell heavily wo days, and the peaks behind the lower range that in Nice in the north are already white with new- n snow.

ıe following letters are from Naples :—

egret to say that other cases of cholera have occurred ın Giovanni, and, though not numerous, sufficient to e great uneasiness. The authorities, who at first ed the fact, have now been compelled to publish daily tins, and are doing all they possibly can to confine estilence within its present limits. Following out the dage of closing the stable door when the horse has stolen, they have now begun to fill the stagnant pools ater, and to remove or disinfect the pestiferous estab- ments in the neighbourhood. As a matter of pre- on, too, the Bersaglieri, who were quartered in the mili," near San Giovanni, have been sent off to nto. Such are the ignorance and superstition of people, taken advantage of in this time of panic by ical adventurers, that both the municipality and the icians have been exposed to not a little abuse and er. Poison, it is asserted and believed by many, has put into the food, or scattered about in public places I have myself met with those who have declared that saw it poured into the wine in the wine-shops. With people it is impossible to argue. This idea is by no is a new one, having been generally entertained in this try in past times during any prevalent epidemic, and ontinue to be entertained so long as civilisation is at w an ebb. All that can be done is to provide by the e force against any danger which may arise from the ng panics of an ignorant populace. Naples is, I am g to believe, still free from cholera ; two cases were, ver, said to have appeared on Friday—one in the San Loreto, and another in the Quarter of the Stelia. are not so decided, perhaps, as to justify me in ing them to be cholera. Both of the persons attacked of the poorest class, and had arrived from San Gio- . Meanwhile the authorities of the city are making provision for preserving the public health. Com- ners have been appointed to inspect every article of and commit great havoc among the contents of the

In the Quarter of San Ferdinand alone 8,500 loaves irty sacks of flour were destroyed on Thursday, to othing of meat and fish in other parts of Naples. nts continue to arrive of the existence of cholera in astern Provinces, and of its re-appearance in slight tions where it had disappeared, as in Lucena. The reports from Barletta speak of twenty-two deaths in y, and from Brindisi of four. Bitetto, Giovanazzo, Bisceglia had their victims, and Melfi, a town of asilicata, with a population of 10,000 persons had een attacked. If this is confirmed it will be the o be regretted, as it would show a tendency of cholera ls the centre of Southern Italy.

rything is in such a state of uncertainty that it is lt to obtain satisfactory information about the rtine, but up to the present time none has been put ween this city and Rome, travellers being subjected sole inconvenience of fumigation on the frontier. tate of things is not, however, likely to continue long, and some English families, anxious to get to Rome, left in a hurry on Saturday morning. Vessels from Naples to Genoa are subjected to eight days' quarantine, while at Leghorn they are refused ; the same on the coast of Calabria and in Sicily. At the same time, vessels arriving from any part of Italy are received in Naples, while those coming from Southampton, Cardiff, or Swansea are subjected to fifteen day's quarantine.

It is but too true that cholera has at length entered this city, and, though up to the present time its victims can be counted on the fingers, the reminiscences of its former visits are such as to create considerable apprehension. As yet I have not heard of more than four cases—one, of a woman who died in the hospital of San Loreto ; another of a woman who was attacked after drinking a bottle of rum ; another case was that of a man near the Ponte di Maddalena ; and a fourth, that of the Marchesina Auletta. All four resided in the upper part of the city, near the Toledo and the Infrascati ; and in one or two cases certainly death may be traced to intemperance. We are now waiting with anxiety to see what the progress of the malady will be ; it is hoped, say the Medical men that it will not extend much, and that it will soon disappear from amongst us, but hope can do little in such circumstances, except to give moral courage to meet the danger.

Certainly the sanitary conditions of Naples are much better than they were on either of the former occasions when cholera gathered in its harvest, and all who are in authority are acting with admirable prudence and energy ; but the neglect of the past may be expected to be followed by its just consequences, and the absence of any system of sewerage increases the danger which must needs exist at such a time. Of the organisation adopted to meet the necessity of the occasion I have already spoken. A hundred beds have been prepared in the Hospital of Pie-di-Grotta and the Hospitals of Loreto and Pacella are in readiness to receive patients. Lemons, sugar, and linen are stored in every section ; the mills are constantly examined to ascertain the quality of the flour ; in every case of death the houses have been insulated and disinfected, and the clothes of the victims taken to the outside of the city and burnt ; so that all that can be done is being done, and with sobriety, cleanliness, and courage, which are everywhere preached, it is hoped that the malady may be of short duration.

The report from San Giovanni, sent to me by one of the Medical men appointed to watch over San Giovanni, is far from being of an encouraging nature. In four days there had been, he says, thirty cases in a population of 10,000. The disease is of a very violent character, and the great proportion of those attacked succumb. It increases from day to day, especially in a street called Castina della Marchesa, which seems to be the centre of it. A hospital has been established in a convent of the Padri de Cuiesi, and at the moment of my friend's writing, there were seven cases in it under treatment. The Commissioners of Charity, of Health, and of the Municipality, were using great exertions to supply the sick with everything needful ; nevertheless, the disease was spreading rapidly. Great faith has been placed by many in the cleansing and healthy influences of the abundant rains we have had, and also in the great fall of the temperature. It was forgotten, however, that heavy rain, after the long-continued tropical heat we have had, would be followed by decomposition of animal and vegetable matter ; and it seems to have been forgotten also that on its first visitation, in 1837, cholera carried off most victims in the winter. I do not wish, however, to appear as the prophet of evil, and in truth, while the cases are at present few in number, the sanitary conditions of the city are far superior to what they were in the fatal year above mentioned.

The state of the health of those in the Lazzaretto, and of the crews of the ships in quarantine is excellent. Our fleet is still here, but I am told that the admiral is anxious to leave, and one of the officers says that they may be off at twelve hours' notice.

When I last wrote I was uncertain about the reception which travellers would meet with on the southern frontier

of the Papal States, but all doubt was set at rest by a despatch sent to the Spanish Consul, who acts here in the place of the Pontifical Consul, announcing that all travellers from Naples would be refused entrance. As a consequence, therefore, a large train of passengers which left yesterday morning for Rome, on arriving at Ceprano, was sent back, and many an unhappy excursionist is therefore imprisoned in Naples. Marseilles, Genoa, Leghorn, and the Roman States are closed.

We subjoin the following able remarks on the recent epidemic of cholera, by Dr. Letheby in his last report On the Sanitary Condition of the City of London for the quarter ending September, 1865 :—

Cholera, in an epidemic form, has appeared in the towns and villages upon the eastern shores of the Mediterranean; and as most of those places are in frequent communication with the neighbouring ports of Europe, it has been feared that the pestilence would move forward in the usual tracts of commerce, and ere long appear among us. That there are good grounds for such alarm there can be no doubt, and it would be highly imprudent to disregard the proximity of so dangerous an enemy, notwithstanding that the circumstances under which it has manifested itself are not at all like those of former visitations.

It is proper to remember that in the great epidemics of 1831-32, and 1848-49, there were three facts which came prominently before us :—1. There was an unusual outbreak of the disease in India, where it showed itself in an epidemic form; and this lasted for a year or two before its appearance in Europe. 2. The course of the disease was always from India in a north-westerly direction, through Russia and by the Baltic into one or more of our Eastern ports. 3. At the time of its appearance among us there was a large amount of zymotic disease, especially diarrhœa and dysentery.

At present, however, there are none of these significant forewarnings of an approaching epidemic. India has for the last four years been rather less than usually infected with cholera; for although the disease has never been entirely absent from the Indian Peninsula, since its first appearance in the Delta of the Ganges in 1817, and has yearly caused a large mortality not only of our troops but also of the native population, yet it has not assumed an epidemic character since the year 1861.

Again, in both of the former visitations of the disease, the course of it has been from the north-western provinces of India, through Persia, and along the western shores of the Caspian Sea to Astrachan, where it has rested for some time. It has then traversed Russia by the Volga and its tributaries, and has reached Moscow in September. Here it has again halted for the winter; and in the following spring it has moved forward in a north-westerly direction, and has arrived at St. Petersburgh in the months of June or July. It has thence branched off in two directions—north-westerly through Finland, and by the Gulf of Bothnia into the north of Sweden, where it has soon exhausted itself, and south-westerly by the Baltic into Sweden, Prussia and Denmark, and so across the German ocean into one or more of the ports on the eastern coast of England. Its progress along this route has not been rapid, for independently of the time of its existence as a severe epidemic in India, it has taken from two to three years to perform its European journey.

While the epidemic has been thus pursuing its more northerly course from India, it has also been journeying into Europe by a more westerly route through Asia Minor. Starting as before, from its home in the north-western provinces of India, it has coursed along the shores of the Persian Gulf to Bussora, and thence by the Tigris and Euphrates into Asia Minor, spreading southward by the eastern coast of the Mediterranean into Egypt, and northward through Asiatic Turkey to the shores of the Black Sea. Following the coast line of the country from Constantinople, it has soon reached the mouths of the Danube, and has thence passed through European Turkey and Hungary into Austria, and so onward into the smaller states of Germany; while Italy, France, and Spain have been open to its progress by the shores of the Mediterranean.

But although this has been the general course of the cholera epidemics of former years, it has also been noticed that the disease has frequently exhibited the most erratic movements, Sometimes it has turned back upon itself, and reappeared with extraordinary virulence in places where it had almost died out. At other times it has jumped over considerable spaces of territory, and has shown itself, at nearly the same date, in places widely apart; but still with all this apparent capriciousness there have generally been certain well marked laws of its progress which have not only characterised its movements, but have given notice of its visitations.

On the present occasion, however, the course of the epidemic has been confined almost entirely to the eastern shores of the Mediterranean; and it appears to have acquired its virulence among the pilgrims who were assembled at Mecca and upon Mount Ararat, to celebrate the Mussulman festival of Kourban-Bairam, or the festival of Sacrifice. This festival lasts for the first twenty days of May, and it generally brings together from 600,000 to 700,000 persons from all parts of Asia and Africa. The pilgrims are mostly of the very lowest classes of Mahometans; and irrespective of their filthy habits, the very rites of the festival create a condition of things which soon begets disease. Crowded as they are together, feeding on the poorest diet, drinking water polluted with corruption, scattering about them the filth of their camps, and the remains of their animal sacrifices, and living in utter violation of all the rules of hygiene, it is not surprising that there is always an enormous amount of disease and mortality among them; but this year, in addition to the common sickness of the season from fever and diarrhœa, there was an outbreak of cholera, or as the government of the country have very mildly reported it, cholerina. Some of the devotees had journied from India, and had brought with them the germs of the disease. Indeed, it is said, that in one of the ships while off Moculla, on the Arabian coast, as many as eighty of the pilgrims died from cholera. It was thus carried to the Holy places; and it would seem from official reports that not less than 40,000 persons died from it—private accounts say 100,000, but this is perhaps an exaggeration. There is no doubt, however, that the disease was severely fatal, and that it assumed an epidemic character; for soon after the pilgrims began to disperse, it appeared at Alexandria, which is only separated from the northern extremity of the Red Sea by the narrow Isthmus of Suez; indeed it is possible that it may have crossed the Red Sea at Mecca, and have gone down the Nile by its western branch; for contemporaneously with its appearance at Alexandria early in June it showed itself at Rosetta and the neighbouring villages of Tanta and Zagarig. At Alexandria, the outbreak was in the poorest and filthiest quarter of the city, namely, in the north-western suburbs, near to the railway station, where there is a mixed population of Arabs, Turks, and Greeks; and it seems that the city was in a fit condition to welcome the pestilence, for not only was the temperature high, and the filth abundant, but the canal of the Nile from which the city is supplied with water was more than ordinarily polluted. There had been a fatal sickness among the cattle, and their carcases were thrown into the river—as many as seven hundred of them in a state of horrible putrefaction were seen in it at one time. It is, therefore, not surprising that the epidemic increased in violence; although its force was chiefly expended in the crowded and dirty parts of the city, for it barely touched the cleaner quarters in which the Europeans reside. On the 17th of June it had moved inwards by the river to Cairo, and soon afterwards it returned by the eastern arm of the Nile to Damietta, where it was remarkably fatal. It then crossed the eastern extremity of the Mediterranean to Smyrna, which it reached on the 24th of June, and four days afterwards it had turned back upon Cyprus. Early in July, about the 10th, it was at Constantinople and the villages of the Bosphorus; and a little later it was at Ancona, in Italy, and at Malta. From Malta, where it was very

severe, it soon passed to the neighbouring island of Gozo, and thence to Catania, Palermo, and Trapani, which are coast towns of Sicily.

This seems for the present to be nearly the end of its course, for although it has appeared at a few places in Northern Italy, and at Marseilles, Toulon, and Gibraltar, yet its chief manifestations have been to the eastward of the island of Sicily, and has rarely advanced far from the sea-coast to the interior of the country. It may therefore be concluded that for the present the epidemic is confined not only to the basin of the Mediterranean, but chiefly to the Eastern end of it; and that as yet it has shown but little tendency to move northward and westward into Europe. So far then the prospect is hopeful, but it can hardly be said that the danger is altogether past; for if on the return of spring the disease should again appear at Constantinople, and should creep along the Eastern coast of the Black Sea, it may take its usual route by the Danube to Europe, and so reach us from the Western States of Germany. It may also re-appear upon the Northern shores of the Mediterranean, and thence travel into Italy, France or Spain. But if we are thus forewarned by a knowledge of the probable progress of the disease, we may be also forearmed by a knowledge of its invariable habits; for the lesson taught us on the present occasion, is exactly a repetition of what we have learnt from the past: everywhere we perceive that the haunts of cholera, are the haunts of wretchedness and filth—that the strongholds of the disease are in the crowded and ill-conditioned quarters of the poor—that where fever, and plague, and all the exanthemata abound, there also does cholera appear in its greatest force. That in fact, although there is some capriciousness in its manifestations yet it implicitly obeys the law of other epidemics, and strikes hardest where there is poverty and filth, and ignorance and fear. This has been but too fully illustrated by the havoc of the disease in the poorer quarters of Alexandria, Cairo, Smyrna, and Constantinople. It may be that there are no parts of this metropolis like the wretched courts and alleys of those eastern cities, where every rule of sanitary economy has been habitually violated; and yet we are forced to admit, that notwithstanding our large sanitary improvements, there are but too many places among us where there is still enough of want, and ignorance and filth to be a source of danger at the commencement of the disease. Indeed that which especially commands our attention is the necessity for a systematic and repeated examination of these places, so that there may be a constant removal of all exciting causes of disease; for unfortunately the negligence and ignorance of the poor stand so much in the way of sanitary improvement that nothing but a continual supervision of their homes and the exercise of the most peremptory measures, will maintain them in a safe or even moderately wholesome condition.

CYCLOPS' TWENTY-FIFTH LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—My last letter contained many important, and not to the general reader, many strange ideas; as well it might be! because they sap the foundation of much of our physiology of the age, that is, the ages's belief in a number of things which it calls physiology, but which has no right whatever to the name, for true physiology will some day be denied of their very association. Present belief in many things, upheld by the powers that be through want of knowledge of natural laws, will sink into nothingness when replaced by more logical and, consequently, more truthful theories. However, let that be. Whatever is new must be tested and pass through the usual ordeal of new error.

Before pursuing the subject with which I terminated my last letter, I must refer to a remark made in a former one, that physiology is based on inquiry and the asking of many questions, not of men, but of Nature. The first, which would strike everybody, is, what becomes of the vast amount of oxygen we consume in every possible way every moment of our lives? for let it be remembered, we are not exhalers of oxygen but consumers. We could not breathe without oxygen, and in chemical and other works, records have been given of what the lungs can do in this way. Well, and if they do all that is said of them, oxygen seems only a natural element to excite respiration, for we see that immediate conversion takes place after every inspiration, and we expire a different gas. All this is as old as the hills, and great is the quantity taken, but it is not a tithe of what is consumed by other parts of the body. We are always swallowing; deglutition of some moisture is always taking place; and if no perfect or actual deglutition occurs, still, there is a constant trickling down the gullet of moisture of some sort. Every mouthful we take we carry down oxygen with it; but let us drink off a tumbler full of water or anything else, it is done in a second sometimes, what a vast amount of oxygen goes down our open throats then! There are times when the body is in a passive condition and consequently in a state of endosmose, so that we absorb it largely. In our ablutions or baths we do the same. I do not believe that any man can calculate the amount absorbed and taken up into the system, though some ingenious men have tried to calculate the radiation or exosmose of matter from their bodies. Well, we naturally ask, what becomes of that which we take, absorb and consume? It cannot remain pure in the system as it is received; therefore, it must be immediately converted to some special purpose and neutralised by some other gas with which it has some great affinity and in this union form some other element. Whichever way it is disposed of, we naturally ask, Well what then becomes of it? Now as Nature herself will answer the question best, I shall leave her to do it:—

"It is a vital agent truly, but animal life requires more than this, I found it was impossible to make animals without much moisture, I made a framework of solid structure, namely, the bones, and surrounded them with muscles or flesh by condensing the fluids, and for the flexibility of these, I made them of the greatest variety of forms and sizes, so that all animals might be capable of using their varied powers according to given laws, but the amount of fluid constantly required for their lubrication was so immense that I had to keep them constantly supplied with it. I made the arteries to carry a regenerative power to structure alone, and when they had done this I required their more fluid residuary elements as diluting agents to those elements formed from the fresh ingesta. I apportioned certain organs to make their own secretions from other sources than the arterial currents, for if these had to make secretions and lubricating fluids as well as organic structure, I should have had no venous blood at all, it would, in fact, have all been consumed in these acts. Therefore, I kept up a balance in these two distinct currents, one going from the heart and the other to it. But, as animals required as much or even more fluid in their systems for their daily use, than is contained in either my arteries or my veins, I provided for this in a manner physiology has not yet pointed out. Living, as I have made all animals and, in fact, all life and everything that has a vital and living principle, in an atmosphere and this atmosphere known to mortals as gaseous, can it be supposed for a moment that I have done this in the contracted and limited manner men have set forth. No, I have a thousand other resources for the formation of fluids as well as uses for them. Mortals have discovered to some extent the ratio in which gases combine with one another, and that in my laws nothing remains the same from one moment to another, but whatever I have made is constantly undergoing some law of metamorphosis. This then is especially applied to the gases and therein you will see my great wonders, for the gases of the body seem to have eluded men's thoughts. It was for this purpose I made the colon to receive the fæces and from these fæces there should be eliminated sufficient hydrogen and other gases for the purposes of combining with the oxygen absorbed into the body and thus supplying it with fluids of such pure and excellent quality and quantity as to form the natural moisture to all the tissues and parts. The design of the colon may now be seen, that it should be always more or

less filled with fæces for this purpose. The amount of hydrogen is therefore regulated by each individual's idiosyncrasy to mix with the quantity of oxygen his system can absorb or use. Some idiosyncrasies absorb oxygen so readily, while at the same time then fæces radiate the hydrogen so quickly that they get by the union of these gases enough fluid elements for the functions and uses of the body generally. In these, the regularity is so perfect that, if the fæces eliminated more hydrogen than was necessary, there would be a want of balance in the system, therefore directly these are accomplished, I dictate the removal of the superfluous fæces from the colon, otherwise excess of hydrogen would be the result, and the health of such a person would necessarilly suffer from their retention. So you see I care not how fæces are made, or what they are made from, as long as they are made and are duly deposited in their proper receptacle. What does it matter to me what food an animal takes, each after its kind, whether carnivorus, graminivorous, or omnivorous. Their organisms are perfect for each and what they like and what agrees with them I, Nature, assert they ought to take, for I have sent all things that are good for all and every one of my creatures If more aliment is taken by any individual and consequently more fæces made than he requires when in health, his natural state gets rid of them oftener, as things that he does not want or has in excess. The hydrogens being so elastic, so volatile, so penetrating and the porous structures of the body so permeable, that the moment they find their way through them they meet with oxygen everywhere, and thus I am enabled to make very many pints of fluids throughout every structure in the body every day, and by this means I lubricate every part with a moisture and a fluid entirely independent of the blood, which is used and exhausted incessantly in a thousand ways. By this means it is, I make the body so plump and round, so full and the form so generally and so well maintained. The artist and the sculptor are more indebted to my gases and independent fluids, than they are to all the arteries and veins, or the plentiful and beautiful currents they convey. Do they delight in painting or sculpturing poor, lean, haggard bodies, frames or faces? No! they prefer those forms which the full benefit of my gases alone can exhibit to them. Look at the beautiful plump, well-rounded figure, with all its graceful proportions, every muscle of the body and feature of the face redundant with my laws of health, produced by regularity in the union of the gases. In a few hours, when a cholera or a severe diarrhœa has removed from the body those gases I designed to resist others, behold then the sunken eyes and cheeks, the flabby muscles, the prostrate frame, presenting an object of pity and disgust rather than admiration. Has bone or flesh or blood ought to do with this? No! all are there, but the oxygen meeting with little or no elements with which to amalgamate, rapidly wears out the very structure it but a short time before was the cause of plumping up and rendering so beautiful. All the elements that made my hydrogens have been removed, and therefore, none can be formed; the skin lies loose, the muscles and tissues having lost their air and moisture; sunken, prostrate and collapsed now lies the frame. Anon, restore all my gases and let them once again unite in all their integrity, and they will again produce their many pints of moisture and fill out the frame once more to all its pristine loveliness. Now, let us take a healthy person and suppose his fæces failed to eliminate a proportionate quantity of hydrogen to the oxygen he consumes, they are then retained for a longer time for the specific purpose of doing so. On the other hand, another may have a regular action of the bowels every day or even twice a day, and this may be accompanied by the best of health. It would be wrong to suppose that a condition of health is in consequence of such regularity; because another individual would not be in health if the same thing took place in him. Such persons have only the best of health when their bowels are more conserved. Therefore, because a large number, having regular daily actions of their bowels are so well, it is no reason why others, equally well with the deferred act, should be brought to their condition. It is just as absurd and hurtful to bring the former class of persons to the condition of the conservative class as the conservative ciass to theirs. This is one of the greatest errors in medication which poor mortals have always committed. It has been their bane for thousands of years, because they have never considered the gases of the body in their proper light. Could it be supposed for one moment that I could have made such a provision as the colon or the fæces, if I had not made the atmosphere. My arrangements would have been entirely different. If oxygen and consequently my atmosphere generally was not what it is, in respect to the individual formed to live in it, what would be his state? Why he would be filled with his own hydrogen so quickly that he would bound up into the air or be like a balloon and every one would be knocking about against his neighbour. But all this I have regulated, if man would only take into consideration my laws. There are so many who blame me, because their choicest and most cherished dogmas fail them; this is not my fault, but rather let them blame themselves, if they act counter to all my proceedings. Their doing so, is because they have not studied and observed my acts in the laws of disease, or my beautiful yet simple processes which sustain life and health. They prefer rather to take the authority of men and books than observe me and my wonders for themselves. I notice a general fear amongst all of differing in opinion from the dogmas of schools and schoolmen, for those that do seem marked out for scorn. But he is both bold and wise who permits no such conduct to influence him. Watch me closely in disease and you will find more wonders in the actions of the colon, my great laboratory, for the vital gases, than you will find elsewhere and you will discover many things of which the schools with all their boasted learning have not yet dreamt of."

Listening thus to what Nature said, and reflecting on the failures a great empiricism has entailed upon our best endeavours to treat the sufferings of our fellow mortals, I will endeavour to illustrate some of her marvellous acts bearing upon the points above alluded to.

I am, &c., CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

THE PROPOSED CHOLERA CONGRESS.

The following is a circular addressed by M. Drouyn de Lhuys to the representives of France abroad:—

"Monsieur,—The recent irruption of the cholera into Egypt, whence the malady has successively spread into several other provinces of the Ottoman Empire, as well as into some portions of Europe, has awakened the solicitude of the different Governments as to the dangers to the public health offered by the present insufficiency of the barriers opposed to the development of the scourge. All these Governments, as well as those whose territories up to the present time preserved, may be subsequently threatened, understand that it is their duty to guard the populations against a calamity doubly formidable by the evils it entails and the disturbance it creates in international relations.

"Each Power has thus adopted, either spontaneously or to satisfy the pressing desire of public opinion, such arrangements as have seemed to it most efficacious to defend its territory against the invasion of the malady; but experience has shown that the preventive measures, taken separately and differing according to the locality, are difficult to reconcile with the customs and wants of our age, impatient of every shackle which fetters the liberty of commercial transactions.

"Struck with the inconvenience of this situation, the Government of the Emperor has asked itself whether, at the same time that means are adopted to arrest the evil in its course, it would not be possible to direct attention, first of all, to attacking it at the fountain-head, by combating it

ıergetically in the very places where it arises by a system
measures concerted with the territorial authorities. To
fect this object the Emperor's Government has considered
was urgent to establish a preliminary agreement among
ıe interested Powers, and for this purpose to bring about
ıe meeting of a Conference, in which, besides delegates
om the different States, men of science thought the best
ted to assist in deliberations by their especial knowledge
ight take their seats.

"The object of this Conference would be to investigate
e primary causes of cholera, to determine its principal
ints of departure, to study its characteristics and its
ırch; lastly, it would have to propose practical means
r confining the disease and stifling it at its origin. It is
t our desire to attempt to mark out in advance the pro-
ımme of its labours; we wish to leave that care to the
tinguished members who will be called upon to partici-
te in it, and who certainly receive sufficiently ample in-
uctions to enable their studies to embrace all the ques-
ns requisite to be examined and resolved. It is, how-
r, already at present perfectly understood that the Con-
ence, while preserving the utmost liberty in its views,
ll not have to interfere in any act of internal adminis-
tion, nor to take the initiative in any proposition, calcu-
ed to obstruct the free exercise of territorial Sovereignty.
e measures whose adoption it might advise would be
able to be put in practice upon the territory of any
ıte otherwise than by the independent authority of that
ıte itself.

"Owing to their geographical position the countries of
e Levant are first attacked by the scourge. The Oriental
vernments, therefore, are particularly interested in the
ıeliorations it is desired to introduce for the general
lfare in the organisation of the sanitary service, and we
y reckon with confidence upon their co-operation in the
asures of which their subjects will be the first to experi-
ce the beneficial effects. It must not be forgotten that
s owing to the preserving assistance of the Porte, to the
cessive improvements it has introduced into the admin-
ration of the public health, that the problem of the sup-
ession of the plague has been happily settled. It is from
ırkey, therefore, that the Conference will be able to find
e most efficacious aid in its labours; it is with her support
ıt it will collect the best elements of practical solution.
ese considerations, the value of which will no doubt be
preciated by the Cabinet of ——, appear to me naturally
point out the city of Constantinople as the seat of the
nference. Brought into more immediate contact in this
ital of the Ottoman Empire with the provinces in
ich the epidemic has its chief centres, the representa-
s of the foreign powers will gain valuable information
n the superior Council of Health, working under the
preme direction of the Porte. These favourable condi-
ns will render easier in that city than anywhere else the
omplishment of the important mission to whose success
administration of the Sultan will consider it an honour
ontribute.

I request you, Sir, to be good enough to communicate
e views to the Cabinet of ——. We shall learn with
ıt satisfaction that it gives its assent to them. In the
nt that, as we are willing to hope, the adhesion of the
erent Powers should allow of the Conference meeting
hin a short period, I shall acquaint you with the choice
le of our delegates.

You will find annexed a copy of the report which, con-
ntly with his Excellency M. le Ministre of Agriculture,
nmerce, and Public Works, I have had the honour to
sent upon this subject to the Emperor, who has deigned
ıpprove its conclusions. This document is not intended
be communicated to the Government to which you are
redited, but you may base upon it the arguments which
port the views set forth in this despatch.

"Receive, &c.,

"Drouyn de Lhuys."

THE DEATH OF LORD PALMERSTON.

The death of Lord Palmerston in its suddenness and the violence of the blow bears a striking analogy to that of the late Prince Consort, and we hope on the scrutiny of competent judges less room will be found for doubts as to the responsibility of our Profession for the result than in the death of the Prince Consort. We would be understood to speak strictly on speculation, and to convey no censure, unless future investigation shall prove that it is deserved; but we cannot but remark that the character and prognosis of the disease seems to have as completely escaped the Medical attendants as it did in the parallel case of Prince Albert. The first public intimation of the Premier's illness is conveyed by the following bulletin, issued at five o'clock in the evening of Tuesday, the 17th:—

"In consequence of having taken cold, Lord Palmerston has been seriously ill: but he has steadily improved during the last three days, and is now much better.

"T. Watson, M.D.
"Protheroe Smith, M.D.

"Brocket Hall, Oct. 17th."

We learned from this notice that Lord Palmerston had been seriously ill for three days, but that his illness was not of such gravity as to justify an earlier bulletin. At six o'clock on the 17th, the physicians in attendance, full of confidence, thought not of the complication which five hours afterwards had not only declared itself but run an alarming course. The symptoms of the opproaching death-stroke had either not shown themselves or had not been even remotely appreciated at six o'clock in the evening, which at twelve had changed the augury from life to death. The second bulletin was issued late on Tuesday night:

"Lord Palmerston's illness has became worse since the morning. Telegraphic messages have been sent to the Queen in Scotland since Sunday, and Sir George Grey has been communicated with through the same medium. Without any desire to cause pain to the friends of the noble Premier, it cannot be disguised that he is very seriously ill."

The rest is known—the treatment which was not anticipated came too late, and the Premier who was declared to be "much improved" at six on Tuesday evening was dead at twelve on Wednesday. We repeat that we desire not to censure. Physician are but men, and a man of eighty-one may die in in a dozen hours of a seizure which had not even been suspected before; but we shall look with painful suspense for some plain and straightforward explanationwhich may serve to wipe off the suspicion of inefficiency or over-confidence certain to remain on the public mind in the absence of further information. What did Lord Palmerston die of? We are simply told that he had "taken cold"—that the secondary complication was "an affection of the bladder"—and that for several hours before death he was comatose. Was the "cold" a chill suppressing perspiration and throwing work on the kidneys which they were unable to discharge and which resulted in uræmic poisoning? If so, the possibility of such a result should not have been left unguarded. In the interests of the Profession we look for some more satisfactorily information than was afforded in the case of the Prince Consort.—'Medical Press.'

(The above strictures, although not altogether uncalled for, are not quite in accordance with the actual facts.—Ed. Med. Circular.)

Marseilles and Toulon.—Both these cities have petitioned the Emperor, praying for restrictive measures when epidemic diseases break out in the East. The petition contains a very touching sketch of the sufferings of the inhabitants, and the havoc occasioned among them by contagious diseases imported by vessels coming from infected countries.

Medical Charities.—The late Nathaniel Soames, Esq., of Warwick gardens, Kensington, has bequeathed to the Great Northern Hospital 4,000*l.*, to University College Hospital 4,000*l.*, and to the West London Hospital, Hammersmith, 2,000*l.*

WEDNESDAY, NOVEMBER 1, 1865.

THE MEDICAL CIRCULAR.

DEATH IN OUR RANKS.

The grave has just closed over one of the most distinguished statesmen who has ever guided the helm of public affairs in Great Britain, and we have nothing to add to the numerous and able eulogies which have been called forth by Lord Palmerston's death, at a ripe old age, and at a time when the deceased was in the enjoyment of the highest honour which the State could confer, and of all the respect which the nation at large could bestow. It is our melancholy duty this week to touch upon a kindred theme, and although of a humbler nature, it is one that more nearly touches ourselves—namely, the losses which death has just inflicted upon our Profession by removing from among us some of its most respected members, two of whom might fairly be said to have met their death in the performance of their duties, and from maladies contracted in their struggles with disease.

The first on the list in point of seniority is Mr. William Newnham, late of Farnham, a gentleman who had attained to a considerable age, and had enjoyed a very extensive practice, but who, for some years past, had been suffering from chronic disease of the brain, and finally sunk under an attack of paralysis, supervening upon, or associated with, the original affection under which he laboured. Mr. Newnham's name will long be recollected by a large circle of professional friends, on account of the geniality and kindness of his disposition, but his memory is more particularly associated with the Medical Benevolent Fund, which he originated, and of which he was for many years the Treasurer, and latterly one of the Vice-Presidents, and always, while his health lasted, one of its most active and efficient supporters. In case any of our readers are unacquainted with the nature and objects of this Fund, we may state that it was founded for the purpose of granting relief to distressed members of our Profession, and that it differs in many respects from any other institution of a similar nature. There are scarcely any expenses of management, indeed, we believe we may almost say that there are none; and relief is afforded, sometime immediately, and always privately, in any necessitous cases properly recommended. With this excellent institution Mr. Newnham was long connected, and its present prosperity has been in no small degree promoted by his constant assistance and advocacy.

The death of Mr. Francis Cooper, of Southampton, is a melancholy instance of an active, zealous, and indefatigable, though shamefully ill-paid public officer, dying at his post, and falling a victim to the very fatal disease he was endeavouring to investigate, and the ravages of which he was doing his best to anticipate and prevent. It is but too well known that Southampton has been distinguished by the inauspicious pre-eminence of being almost the only town in England yet visited, during the present year, by Asiatic cholera, and while he was actually engaged in tracing out the malarious conditions which might generate, or at least propagate the disease, Mr. Cooper appears to have inhaled a fatal dose of the subtle and mysterious epidemic poison, from the effects of which he never rallied. The circumstances of his death lend no support to the doctrines of those who maintain the contagiousness of cholera, for, so far as we know, Mr. Cooper had not been in actual attendance on cholera-patients; but on the other hand, such mere negative evidence does not outweigh the positive statements of those who bring forward actual proof of the propagation of the disease by contagion.

One thing however is certain—namely, that Mr. Cooper, at a time when the cholera-poison was present in the atmosphere or the waters of Southampton, was actively engaged in tracing the origin of the disease and devising means for arresting or preventing its attacks, and while earnestly exerting himself in this humane and beneficent work he fell a sacrifice to his own zeal. The nation which shows so much generous and just sympathy for those who have died in its service in periods of war, ought not to grudge its condolence, and if necessary, its more substantial acknowledgements, to those who have perished while fighting with epidemics in the time of peace. For the dangers are pretty nearly the same, whether the contest is with a visible enemy on the field of battle, or with the equally deadly but invisible foe, which in the form of the pestilence visits us upon the wings of the wind, and spreads death and desolation along its path. It will, perhaps, scarcely be believed that for the arduous services rendered by Mr. Cooper he at first received nothing at all! that afterwards he had a salary of 150*l.* a year, which at the time of his death had been augmented to 200*l.*, and we need hardly add that the salary dies with him.

But the last name we have to record in our present painful list is that of one who has been cut off almost in his prime, and while the field of labour in which he was actively engaged had been only partially worked, and from which a rich harvest might have been reasonably expected to spring up. The death of Dr. Herbert Barker, of Belford, touches more nearly the fountains of our own sympathies than even the decease of the other lamented gentlemen to whom we have paid our brief tribute of sorrow and respect. Dr. Barker had barely passed the middle period of life, but had already attained to some of the highest honorary distinctions which the Profession had to bestow. Like Mr. Cooper, of Southampton, he died from the very disease which he was endeavouring to investigate in order to ward off its attacks from his fellow-countrymen. By a careful examination of all the meteorological conditions of the atmosphere through a long series of years, and by comparing these conditions with the prevalence of disease, Dr. Barker was materially co-operating in the completion of statistical data in reference to epidemics, the exact nature

f which he was still further endeavouring to elucidate by umerous practical observations and chemical experiments. ut the magnitude and extent of his researches, combined ith the incessant demands of a laborious practice, proved o much for a constitution which appeared to be, mentally d corporeally, one of the most robust, and he sunk, ther suddenly and unexpectedly, from an attack of typhoid ver, the crisis of which he was thought to have successfully passed. In another column we have given some w particulars of Dr. Barker's life, of his labours, and of his ath, and we can only add in this place that, as the race not to the swift nor the battle to the strong, Dr. Barker's sition in the Profession was far from being what was erited by his extensive learning and his practical skill in ery department of Medicine and Surgery. The amount work, mental and physical, undertaken by Dr. Barker, as enormous, and we should have been but too well eased if we had seen some adequate rewards conferred on him during life, instead of our recording the language encomium, however sincere, pronounced over his unely grave.

OBITUARY.

DR. HERBERT BARKER, OF BEDFORD.

MONG provincial practitioners few men have held a more nspicuous place than Dr. Barker, and perhaps no one has ssed from us who, for variety of attainment in Medical d general science, has been more honourably distinguished. is barely three months ago since Dr. Barker stood at the eeting of the British Association at Leamington, one of e most active members of that body, and received e Hastings Medal from the founder of the Association. was observed by many on that occasion that Dr. rker did not exhibit his usual power, and that he spoke idently with an effort; but no one took further notice an that he looked wearied, and, like many more of e same assembly, overworked and charged with professnal anxiety. We learn, writes the 'Medical Times and zette,' that he followed his usual active professional engements until about three weeks ago, when he began to fer from headache, with pains in the limbs at night. He d little attention to these symptoms, and tried to shake em off by continuance of work; still they continued, and time excited in his mind considerable apprehension as to condition. Last Friday fortnight he took to his bed, nptoms of typhoid fever having manifested themselves. the following Sunday by his own wish, Dr. Murchison ited him, and had the satisfaction of giving a favourable gnosis, as there was nothing to indicate a severe attack he disease, although its nature was pretty clearly defined. ring the ensuing week the symptoms became more marked, l the exacerbations in the afternoon were very distinct, he continued to take nourishment freely. On the foling Sunday he was again visited by Dr. Murchison, who nd him reduced in strength, but thought that, as he had ched the twentieth day of the attack, the symptoms ild subside—an opinion which his ordinary Medical ndants, his partner Dr. Goldsmith, and his friend neighbour Mr. Couchman, were happy to endorse. He tinued in much the same way until the following Wedday, when the pulse rose rapidly to 112, and he then dually began to sink until Tuesday week, when he ired.

Dr. Barker has been so long and so well known in the lical Profession that the record of his labours requires e comment. His name had, in fact, become a household word among us, especially in reference to the investigation of the type of diseases of the epidemic class, before one of which he succumbed. He was educated at University College, London, was one of the early graduates of the University of London, a Fellow of the College of Surgeons of England, by exam., a Fellow of the Royal Society of Edinburgh, a Member of the Royal Medical and Chirurgical Society of London, of the Medical Society of London, of the British Medical Association, and of the Obstetrical Society. In the year 1859 he obtained the Fothergillian gold medal of the Medical Society for an essay "On Malaria," and this essay was expanded in 1863 into a work on "Malaria and Miasmata and their Influence in the Production of Typhus and Typhoid Fevers, Cholera, and the Exanthemata." It was in this essay that he recorded his well-known series of experiments on the effects of sewer gases on animal life. His last scientific work was the Hastings prize essay, still unpublished, "On Disinfection and Deodorisation," upon which the judges of the prize passed an opinion of the most favourable kind. He contributed also to many other departments of science, and was one of the originators of those series of meteorological observations on which the system of storm signals, devised by Admiral Fitzroy, and now known to be so valuable for the preservation of human life from shipwreck, is based. For his exertionsin meteorology he received a handsome testimonial from numerous scientific friends, at the instance of Dr. Barker, of Worthing, who, though bearing the same name, was not related to him. He contributed further to Medical and Surgical science, having been, we believe, at one time a collaborateur or assistant with Dr. Copland in some parts of his well-known Cyclopædia; and one of the sections of Druitt's "Surgeon's Vade-Mecum," relating to phosphatic calculus, is connected intimately with Barker's name.

"As a practitioner of Medical science," writes the 'Lancet,' "Dr. Barker was essentially a representative man. Making no pretence to special attainments, he knew probably every specialty with a comprehensiveness which would have put many specialists to shame. As a surgical operator he was cool, collected, and skilful; and the writer of this notice has seen him perform many of the most difficult operations with a readiness and brilliancy which in a London hospital theatre would have been applauded to the echo. In obstetric practice he was prepared for every emergency, and as a physician there was nothing that escaped his acute notice. In physical diagnosis his knowledge reached the highest standard; and his treatment was as simple as it was direct and common sense. The above are the qualities which eminently distinguish the Medical practitioner, and are sufficient to make a man great, however unpretending his practice and position; but Dr. Barker added to these a sincere love for general science. He was a physiologist of no common order; and was one of the best meteorologists living. In addition to these scientific works he had a great love of astronomy, and we remember, on one bright starlight night, receiving from him, through the aid of a small equatorial telescope, a lesson on the nebulæ which the Astronomer Royal need not have been ashamed of imparting. Lastly, he indulged in the study of the philosophical history of medicine, and nothing afforded him greater pleasure than to spend a quiet evening in conversation on the great ones of our past history."

At the time of Dr. Barker's illness, he was engaged in writing, concurrently with photographic illustrations, a series of biographical memoirs of eminent Medical men, but only four numbers of the work had appeared. Of the manner in which Dr. Barker's part of the task was executed, we have lately written, in our reviewing columns, in terms of well-merited approbation, and although the plan was warmly denounced in some quarters, we can only repeat what we have before stated, that the manner in which it was carried out up to the time of Dr. Barker's death, was quite unobjectionable. Dr. Barker leaves a widow (his second wife) and six children, and we fear, from the circumstance that his practice was laborious and not very lucrative, that they are not very adequately provided for. If such be the fact,

it will be only the duty of the Profession and of the public to step forward and help the offspring of one who, when alive had "a hand open as day to melting charity," and whose kindness and benevolence were no less conspicuous than his eminent talents and his unwearied industry.

MR. FRANCIS COOPER, OF SOUTHAMPTON.

Mr. Francis Cooper, the Officer of Health for the borough of Southampton, was seized with illness about two o'clock on Saturday week, when he called his servant and requested her to go for some Medical man, as he was taken very ill, and felt he should not be long in this world. Medical assistance was speedily in attendance, and during Saturday nearly every gentleman in the Profession in Southampton saw him, and remedies of all descriptions were successively applied, but it was painfully evident from the first that the attack would in all probability have a fatal termination. His naturally strong constitution struggled manfully against the malignant disease, but, notwithstanding, he gradually sunk under its ravages, and he died twenty-five minutes before one o'clock on Tuesday week, just three days from the commencement of the attack. The deceased had, it appeared, been suffering slightly from diarrhœa for three or four days previously, he having complained of it as long before as on the Monday evening to his friend, Dr. Wiblin, when spending a few hours at his house. So devoted was he, however, to the performance of the arduous duties of his office, that on the evening of Friday he paid a visit of inspection to a cement factory at Northam, to ascertain the effects of a new invention which had been applied to the works with the view of getting rid of a noxious effluvium, previously generated in the manufacture of the cement, and which detrimentally affected the health of the neighbourhood. Mr. Cooper, who was sixty-four years of age, had been in practice as a surgeon in this town about forty years. He was first appointed Officer of Health in 1850, and performed the duties of that office for nearly eighteen months without any salary. As an illustration of the anxious and arduous work devolving upon such an office in a large town like Southampton, it may be mentioned that its duties consist in visiting all the common lodging-houses, slaughter-houses, and nuisances of every kind, some of them of the worst and foulest description. These visits he had himself calculated at sixty per week, making a gross total of 3,120 per year, and frequently before a nuisance could be removed three or four visits were necessary, and an additional one before magistrates, for which he received no additional remuneration, and according to his own calculations he paid to these different localities something like 4,000 visits in all yearly. He had also to inspect the meat and fish shops and markets in the town. The amount of salary paid him for all this heavy work was 150*l.* per annum up to three or four years ago, when it was increased to 200*l.* It is easy to conceive that with such a multiplicity of duties, considerable injury might accrue to the private practice of any Medical man holding the office, and this was what in reality occurred in Mr. Cooper's case. For a week or two before he was seized with this fatal attack, he now and then complained of exhaustion, and he had a careworn appearance, compared with his usual sturdy robustness, the change being attributable, no doubt, to the harassing nature of his duties and the petty annoyances to which he was occasionally subjected, especially during the last few weeks in the discharge of them. Added to this, one of his two sons, thirty-one years of age, died as lately as the 14th ult. at Leith, which circumstance affected him very much. Mr. Cooper was universally held in the highest respect and esteem by his townsmen, and his death, which is deeply regretted, is regarded as a great local calamity.

ARMY MEDICAL EXAMINATIONS.—The next examination of candidates for the Medical Department of the Army will take place in February, and that for admission to the Royal Staff College in July.

"INJUSTICE OF THE 'TIMES.'"

Under the above heading a pamphlet has been recently published by Mr. Hough, Surgeon, of Cambridge, complaining that an attack was allowed to be made on him in the columns of the above-named Journal, but that his reply was refused insertion. Although only one of our Medical contemporaries has alluded to the subject, the 'Pall Mall Gazette,' which has hitherto shown a friendly feeling towards our Profession, thinks that the 'Times' is in the wrong. We give a brief *résumé* of the narrative.

Six weeks have elapsed since a melancholy accident occured at Cambridge. Mr. Purkiss, of Trinity College, a young man of the highest academical distinction and of rare intellectual promise, was drowned while bathing in the Cam. About two o'clock on Sunday afternoon, Sept. 17th, Mr. Hough was hastily summoned to the spot were the accident occurred—the well-known bathing-shed in the Grantchester meadows, upwards of a mile from his house. When he arrived, the body had just been found, after having been immersed in the river about an hour.

He immediately proceeded to carry out the plans which are recommended by the best authorities, among others, the modes of artificial respiration known as Dr. Marshall Hall's and Dr. Sylvester's, following to the letter the advice given by those gentlemen, and continuing the treatment until he was joined by another Medical man, Mr. Temple. When at length all hope of restoring animation by these means failed, they agreed to try tracheotomy as a last resource. Mr. Hough accordingly opened the trachea, and introduced a quill obtained from one of the bystanders. It should be borne in mind that Mr. Hough was in a field at a considerable distance from any house—the nearest surgery whence a suitable tube could have been obtained being his own, and that (as already stated) upwards of a mile off. There was sufficient proof that the operation was justified by the free admission of air into the lungs; but it is for the surgeon to decide in such cases whether the danger of the condition or of the remedy is the greater, and to act accordingly. In the present instance there was no danger to the patient. A Mr. Lewis, writing to the 'Times,' suggests that such a course as Mr. Hough adopted is likely to be pursued by the inexperienced, and he therefore undertakes, at least indirectly, to condemn it. The improbability of any non-professional person attempting such an operation as *tracheotomy* is too great to need argument. "But it is not with Mr. Lewis," writes Mr. Hough "that I have to do. Had his remarks tended only to cast a slur on myself personally, I could have afforded to let them pass unnoticed. But I felt that a great principle was at stake—a principle tacitly acknowledged by the leading article of the 'Times' of Sept. 20th, but openly assailed by a favoured correspondent of that journal. The principle is one which I trust that English Medical men will ever be bold to maintain at all costs: I mean the right to act in critical cases by reason, and not by rule. No code of instructions can be so worded as to meet all the varieties and all the combinations of accident and disease; and while a secretary of a society is, perhaps, most useful when he is most entirely a machine, a Medical man must claim for himself the right to apply, in his practice, the results not merely of extensive reading, but of daily observation, experience, and reflection, and the application of these to the treatment of actual disease." In defence of these principles, Mr. Hough addressed to the 'Times' newspaper the following letter, but it did not appear in the columns of that paper. It was sent a second time with a like result. This constitutes Mr. Hough's first charge of injustice against the managers of the 'Times.'

"To the Editor of the Times.

"SIR,—In a letter which Mr. Lewis, the Secretary of the 'Royal National Life-boat Institution,' has addressed to you in reference to the late melancholy accident at Cambridge, he has thought fit to animadvert upon the mode of treatment which I adopted.

"In ordinary cases, a Medical man might be content to dismiss non-professional criticism with the advice, '*Ne sutor ultra crepidam*;' but Mr. Lewis's official position may give

is remarks undue weight with lay readers, and on this ccount alone they are entitled to notice.

"Without repeating the evidence which I gave at the in-uest, I will merely state that I carried out the instructions ssued by the 'Royal National Life-boat Institution,' as ir as the place and circumstances admitted; and, when ese failed, I resorted to the last expedient for enabling me ore easily to inflate the lungs, by opening the wind-pipe.

"Mr. Lewis tells us, that none of the Medical men con-lted by the Institution of which he is the secretary, recom-ended cutting 'the apparently drowned man's wind-pipe th the view of inflating the lungs.' I should have been rprised had they recommended the performance of this eration in a paper evidently drawn up for the instruction bystanders at an accident, among whom, perhaps, no rgeon might be present. Surely no surgeon is to be ttered by instructions of this kind. Amid the almost inite variety and combinations both of circumstances and nptoms, his best guide will be his professional knowledge l experience, and not the mere letter of any code of tructions, however excellent.

"I am, Sir,

"Your obedient Servant,

"JAMES HOUGH.

"Cambridge, Sept. 21, 1865."

"The above letter" says Mr. Hough, "was despatched *the t time* from Great Malvern, with a private note to the itor, explaining the discrepancy of the date and post-rk. It was subsequently sent direct from Cambridge, t was not inserted in the 'Times.' On my return home, October 3rd, I learnt that Dr. Humphry, had without y comunication with me, addressed a letter to the 'Times' the same subject. This letter like my own, WAS NOT SERTED." It was as follows:—

'TREATMENT OF THE APPARENTLY DROWNED.

'*To the Editor of the Times.*

SIR,—May I be allowed a few words on the letter in to-'s 'Times' of the Secretary to the "Royal National e-boat Institution," in reference to the melancholy event it has recently occured here?

The procedure adopted by Mr. Hough, when all other ans had failed, of opening the windpipe and inserting a ll for the purpose of carrying on artificial respiration, y not have received the recommendation of any of the lical gentlemen consulted by the National Life-boat itution; yet it must not, therefore, be assumed to be er unauthorised or improper. I find it suggested as a *ier resort* in the very first essay on the subject that I r to. The most effectual, indeed in some cases the really effectual means of carrying on artificial respira-(which is the chief thing to be resorted to in asphyxia) e alternate compression of the throat and careful blow-f air into the lungs through a tube inserted into the hea. Blowing into the mouth or nose cannot be relied

Mr. Hough had been provided with a tube which he l have passed through the larynx into the trachea he ld doubtless have endeavoured to avoid cutting into rachea. That he was not so provided may be inferred his using a quill; the only means by which a quill l be rendered available was by a direct opening into rachea. I think, therefore, that when the other means tificial respiration had been tried and failed, Mr. Hough justified in the step he took, indeed is to be commended

Such a proceeding is not likely to be attempted by ut a Medical man, which may be the reason that it was recommended to be included in the "popular instruc-" issued by the Institution.

n these "popular instructions" for restoring the rently drowned, it is stated that "efforts to promote ath and circulation beyond removing the wet clothes drying the skin must not be made until the first arance of natural breathing; for if circulation of the l be induced before breathing has recommenced, the ration to life will be endangered." Now, forasmuch as is one of the great paralysers and is one of the great excitors of the respiratory and other functions dependent upon the nervous system, and forasmuch as external warmth tends to direct the blood to the surface, and so to relieve the internal organs, I think the wisdom of this instruction may fairly be questioned. The sudden impression of cold, it is true, excites breathing, but it is the impression of cold upon a relatively warm surface. Indeed, further on in the instructions to restore breathing, we find it recommended (most wisely, though somewhat in contradiction to the above quotation), that the attendant should "rub the chest and face warm, and dash cold and hot water alternately on them." If the rest of the surface of the body be cold, the application of external warmth to it is surely one of the means to be resorted to.

'The simplest and easiest mode of conducting artificial respiration is to compress firmly with the hands the fore part and sides of the chest, so as to squeeze the air out, the patient being placed on the back with the mouth open and the tongue held forward, then suddenly remit the pressure when the elasticity of the walls of the chest will cause them to return to their position and draw in the air—the process to be repeated every three or four seconds. I believe that I have been permitted to save—why should I not say to restore?—life in more than one instance by this simple process. If it fails, the other means mentioned in the instructions can be resorted to; and if they fail, an attempt may be made to blow air into the lungs with a proper apparatus, or, in want of such apparatus, by a tube inserted directly into the trachea, as was done by Mr. Hough in his laudable anxiety to prevent this sad loss to our University and our country.

'I am, Sir yours obediently,

'G. M. HUMPHRY., M.D., F.R.S.

'Cambridge, September 20th, 1865."

Considering the rubbish relating to Medical matters which has appeared lately in the columns of the 'Times' we think that the conductors of that Journal might have found room for the above letters, as a mere act of justice, if not for the interests of science.

REVIEW OF BOOKS.

A Description of the Diseased Conditions of the Knee-Joint which require Amputation of the Limb, and those Conditions which are favourable to Excision of the Joint: with an Explanation of the Relative Advantages of both Operations as far as can be ascertained by Cases properly Authenticated. By Peter Charles Price, late Surgeon of the Great Northern Hospital. Edited, with a Preface and Memoir of the Author, by Henry Smith, F.R.C.S., Assistant-Surgeon to King's College Hospital. Pp. 192. London: Churchill and Sons. 1865.

The essay which forms the greater part of this volume was written by the late Mr. Price, in order to obtain the Jacksonian Prize, offered by the Royal College of Surgeons, but the prize was not awarded, on the ground, it is stated, that the conditions for the acquisition of the prize had not been fulfilled, and that Mr. Price had written an essay rather on excision of the knee-joint than on the different diseased conditions which might render that or some other operation advisable. Mr. Price was preparing, during his lifetime, to publish the essay, and thus to appeal from the Committee of the College to the great body of the Profession, but his illness and death delayed the project, which has now been carried out by the wish of his family and friends, under the editorship of Mr. Henry Smith, who was one of the author's warmest friends. Mr. Smith is very severe in his remarks upon the College Committee, and he even attributes the aggravation of Mr. Price's illness to his disappointment at the unjust treatment he had received in the rejection of his essay. But this assumption is perhaps gratuitous, as it is known that Mr. Price was

labouring under serious pulmonary disease for some time before he died.

Mr. Price has so recently passed away from among us, that the few incidents which marked his short but brilliant career, must be in the recollection of many of the Profession. It may be sufficient to state that he was the son of Mr. Price, of Margate, who survives him, that he received his Medical education at King's College, where he especially distinguished himself by his zeal and devotion to Surgery, that he afterwards became surgeon to the newly-established Northern Hospital, and subsequently was appointed Assistant-Surgeon to King's College Hospital, and that after trying in vain the influence of change of climate, he sunk under the effects of phthisis, at Ventnor, towards the end of last year.

While Mr. Price was pursuing his Medical studies at King's College, Mr. Fergusson had revived the operation of excision for incurable disease of the knee-joint, and notwithstanding the fatality which attended some of the earlier cases, Mr. Price was convinced that the operation ought to be substituted for amputation in most instances. He therefore investigated the subject with great care, published several papers in explanation and defence of the operation, and performed it several times himself, his position as Surgeon to the Infirmary for Sick Children, at Margate, giving him considerable opportunities for seeing cases of diseased joints. Mr. Henry Smith thinks he may fairly state, "that next to Mr. Fergusson, Mr. Jones, of Jersey, and Dr. Butcher, of Dublin, Mr. Price has contributed most towards the establishment of excision of the knee-joint as a legitimate proceeding in Surgery;" and it appears from the essay itself that Mr. Price performed the operation during his brief career of Professional practice, no less than seven times, with very encouraging results. He was the first surgeon in England, Mr. Smith tells us, to adopt excision for remedying the deformity produced by an anchylosis of the joint, which renders the limb useless, and since he advocated this plan, it has been followed in several instances by Mr. Fergusson, and in two by Mr. Smith, with the result of preserving very useful limbs to the patients.

The first part of Mr. Price's essay is devoted to a description of the anatomy of the knee-joint, and then follows a sketch of the various diseased conditions of the structures comprising the knee-joint, which under certain phases demand a recourse to amputation of the thigh or excision of the articulation. He also gives a history of all the cases in which excision has been performed in England, Germany, France, and America, with an analysis of the fatal cases, and at the end of the essay he describes the varieties of disease of the knee-joint which are to be treated by amputation, and he concludes by giving the results of his own experience. In reference to the state of health of the patient at the time when the operation is proposed, Mr. Price considers that even the existence of phthisis, in its earlier stages, does not so seriously militate against the proceeding as might be supposed.

We should remark that the essay is illustrated by ten very well-executed coloured plates, besides others interspersed among the text; and the volume forms a valuable contribution to a very important department of operative surgery.

Nice and its Climate; with Appended Remarks on the Chief Causes of Pulmonary Consumption, and on the Action of Climate in that Disease. By Edwin Lee, M.D. Second Edition, with Alterations and Additions. Pp. 179. London: Adams. 1865.

The Health Resorts of the South of France. Notices General and Critical, of Hyères, Cannes, Pau, Biarritz, Arcachon, &c. By Edwin Lee, M.D. Second Edition, with Alterations and Additions. Pp. 213. London: Adams. 1865.

The town of Nice which at one time was extensively resorted to by persons labouring under pulmonary disease, has in some measure lost its prestige in the opinions of climatologists; but on the other hand, it has been numerously frequented by those who are attracted by a gay sea-side residence, possessing many intrinsic and extrinsic charms for visitors. Dr. Lee admits that there exist at Nice some conditions unfavourable to pulmonary invalids, but at the same time he thinks that the climate possesses many advantages for cases which are properly discriminated. He enters at considerable length into the therapeutical properties of the climate of Nice as a remedial agent, not only in chest-diseases, but also in dyspepsia, hypochondriasis, gout, rheumatism, and some cases of paralysis.

Dr. Lee's other book is devoted to the health-resorts lying between the eastern and western divisions of the South of France; the former being much more dry than the latter, which are exposed to the Atlantic Ocean. The little town of Arcachon, situated a little to the south of Bordeaux, and which has lately sprung into some notoriety, is now described for the first time among Dr. Lee's French health-resorts.

Contributions to Dermatology. No. III.—On Psoriasis and Lepra. By T. McCall Anderson, M.D.; Physician to the Dispensary for Skin Diseases, Glasgow, &c. Pp. 65. London: Churchill and Sons. 1865.

Dr. Anderson, having previously published some volumes on the "Parasitic Affections of the Skin," and on "Eczema" (in which he includes Lichen, Impetigo, and Prurigo), now continues the series with a contribution on Psoriasis, of which Lepra is only a variety. The characters of psoriasis are generally well-known and can hardly be mistaken, but it is often difficult to distinguish between the non-specific psoriasis and the syphilitic diseases which resemble it, and Dr. Anderson gives some very clear and precise marks by which the two affections may be discriminated from one another. The treatment of the two is very different, arsenic being the most valuable remedy in the one, and mercury in the other, and indeed, the effects of treatment afford some of the best diagnostic indications. Besides arsenic in the non-specific disease, cod-liver oil and iron are given with advantage, but external applications, although much employed in Vienna, are not much relied on by Dr. Anderson, or, as far as we know, by other British practitioners. The frontispiece consists of a representation of a form of psoriasis which Dr. Anderson calls *P. rupioides*, from its resemblance to rupia, from which, however, it differs in leaving no ulcer, after removing the scab.

The present contribution to Dermatology is written with the same clearness as has been shown by Dr. Anderson in his former productions.

Testament der Natur. Offene Klage vor Gericht wider die Imprergiftung in Würtemburg. Beweis Akten von Dr. Nittinger, in Stuttgart.

Testament of Nature. Public Demand for Justice against the Inoculation-Poisoning in Würtemburg. Acts of Impeachment by Dr. Nittinger, in Stuttgard. Leipzig. 1865.

This is a rhapsodical tissue of abuse against the practice of vaccination, which, according to the author, is the cause of almost all the moral and physical evil in Europe. A great number of quotations are made from a variety of authors, but they are almost all introduced unfairly, and are made to bear an interpretation the reverse of what was intended. The book does not deserve serious notice, and the coarseness of its tone places it beyond the pale of criticism.

Photographs, coloured from Life, of the Diseases of the Skin. By Alexander Balmanno Squire, M.B., Lond. No. IX. London: Churchill and Sons.

The present number of this series presents an illustration of a *nævus vascularis*, belonging to the class of Maculæ,

he subject being a girl, aged fifteen, in whom the dis-oloration was noticed immediately after her birth, and emained without any permanent change since then. Of he portrait we can only say that it is life-like, and no higher raise can be offered. Nævi are divided by Mr. Squire nto two kinds, the pigmentary and the vascular, and the tter are again subdivided into those which appear in the rm of stains on a level with the surface of the skin, and ose which present tumours projecting beyond it. The evus of the illustration belongs to the latter variety, and known as the "port wine mark," and is considered by ost authorities as incurable, and in this view Mr. Squire incides, as the plans he has tried to produce a more vourable result have not been successful.

GENERAL CORRESPONDENCE.

ON DIARRHŒA AND CHOLERA AND THEIR TREATMENT.

To the Editor of the Medical Circular.

SIR,—Having perused two articles lately in the MEDICAL RCULAR on the subject of cholera past and present, may presume to offer a few remarks relative to the above d the treatment I have found recently most effective. uring the past hot and dry month of September, in this arter several cases occurred in my practice of diarrhœa, sting two or three days among the young and middle-ed labouring classes who were previously healthy, and who re attacked suddenly without any assignable cause. All of ese I have treated internally with either acidulated or aline mixtures, combined with sedatives, and occa-nally sinapisms of mustard externally according as the ture of the symptoms individually seemed chiefly to indi-te; each becoming well again speedily. Also the lowing case of cholera, occurring in September last, ay not be deemed uninteresting:—

M. J., middle-aged, stout, and generally in good health; ile engaged in the country (September, 1865), felt lan-id and more tired than was usual with him for a few ys before being attacked; when, previous to his supper al, he was seized with severe vomiting and purging, er which, as evening came on, cramp ensued, and a ssenger was sent off instantly to summon my attendance, l the man on delivering his message, said "he feared he uld be dead before I would be able to reach his house." my arrival soon afterwards he was still vomiting and ging, and violently affected with cramp; voice husky; se feeble; skin cold; stools watery and muco-bilious sing. I procured a warm salted bath quickly and placed in it, which was of great service; but afterwards on returning to bed the vomiting and purging and cramp, ugh stayed more or less, did not seem likely to subside, ordered ice to be got in all haste, which was soon ught by the kindness of a neighbouring landed pro-tor. The ice I now applied in a bladder (which latter vered well) often to his spine, still there was no sign peedy or entire relief; *therefore I gave him the ice to internally, and also ordered two individuals present to a lump of the ice in each of their hands, and rub well arts over the seat of the cramp*, after which he gradually n to be more quiet and free from the latter symptom, the motions from his bowels had almost subsided. ertheless, as there was considerable coldness of his , I applied sinapisms of mustard, which soon induced rmal reaction, and he did well.

I am, &c., G. K H. PATERSON,
heggie, near Perth, N.B., L.R.C.P.E. and L.R.C.S.E.
19th Oct., 1865.

APOTHECARIES' HALL.—The following gentleman passed examination in the Science and Practice of Medicine received a certificate to practise, on the 19th inst:—
Mr Alonzo Taylor, Great Barr, near Birmingham.

PARISIAN MEDICAL NEWS.

A SYNOPSIS OF THE CASES OBSERVED IN THE WARDS OF LA CHARITE HOSPITAL DURING THE YEAR 1864-65.

During the last fortnight of the summer session, M. Velpeau is in the habit of presenting a general return of all the patients admitted into his wards in the course of the preceding twelvemonth. All the cases are carefully taken down by the dressers, and collected by the Professor at the end of each month; at the expiration of the year they are condensed and summarised by the Internes, and supply the elements of an analytical and statistical table, which is thus invested with all desirable guarantees of accuracy. The vast experience which has thus accumulated in the course of thirty years, arranged in an imposing mass of methodically-arranged returns, forms the basis of, and imparts a singularly powerful practical interest to M. Velpeau's tuition.

Our confined space prevents us from presenting the reader with a full reproduction of the figures adduced by the Professor, and of his remarks on the annual return recently laid by him before the public, but we shall at least attempt a brief sketch of this important communication.

M. Velpeau's wards include seventy-five beds, and received during the past year 1,155 patients, 259 of whom merely appeared in the wards, and deserve no particular notice. During the preceding year, 1,014 persons were admitted, and the figure once rose to 1,400. If we accept 1,000 as the average, the total number of cases observed in the course of thirty years would reach 30,000.

As usual, the number of men admitted was greater than that of the women—viz., 797 male and 358 female subjects, and setting aside the 259 individuals who merely passed through the wards and underwent no treatment, 523 men and 373 women.

Eight hundred and ninety-six patients, therefore, were placed under treatment, with the following general results:—

Cured	680	viz.,	489	men	191	women.
Improved	101	„	66	„	35	„
Without change	59	„	32	„	27	„
Died	56	„	34	„	22	„

The mortality is proportionately larger than in former years, and especially greater than in the preceding twelvemonth, when the number of deaths was thirty-two only. The difference is referable to the prevalence of erysipelas, and to the admission of a certain number of individuals who were conveyed to hospital in a dying condition.

Adverting to the classification of diseases, we meet in the first place with the section of fractures, a large division always, including for the present year ninety-five cases, twenty of which only were observed in women. In eighty of these patients a complete cure was effected, ten left the hospital with imperfect consolidation, and five died from the effects of concomitant organic disease. Eleven of these subjects were affected with fracture of the thigh—viz., five fractures of the shaft, and six of the neck of the femur. These eleven cases, together with those observed in previous years, illustrate the good effects of the moderate degree of permanent extension, to which M. Velpeau resorts, not for the unattainable object of restoring the limb to its natural length, but in order to preserve its proper direction. The patient is placed on his back, the thigh extended, and the knee slightly bent, and supported by a cushion. A perineal band passing round the groin, and secured to the head of the bed effects counter-extension, and permanent extension is obtained by bands attached to the malleoli and tied to the foot of the bed. No mechanical contrivance answers the purpose better than this simple apparatus, or is so free from disadvantages. Surgeons are not aware that the lameness consequent on these injuries is less frequently referable to shortening of the limb than to the stiffness and chronic irritation of the joints. During the present year, two or three patients were admitted into M. Velpeau's wards, who presented no lameness, although old fractures had induced a shortening of twelve and fifteen lines. By a remarkable contrivance of

Nature, the pelvis accommodates itself to the change, and no lameness is perceptible. If the lameness persists, it is not, in general, caused by the shortening of the extremity, but by the stiffness of the joints, which can be averted but by the use, for as short a time as possible, of the simplest kinds of apparatus.

These remarks also apply to fractures of both bones of the leg. All the systems of bandaging devised with a view to counteract the action of the muscular textures of the calf of the leg are unavailing and cannot prevent shortening, but this, we repeat, is a fact of secondary importance. M. Velpeau adduced in illustration the case of a man who was badly wounded in the leg by a musket-ball in 1848. The patient recovered with a shortening of two inches; for a long time he limped, but is now no longer lame. The starch-bandage was the only apparatus employed.

A small number of cases of fracture of the clavicle were observed during the past year. Fifteen are mentioned in M. Velpeau's returns, and in all a cure was effected in a fortnight or three weeks. This injury always leaves after it some degree of deformity, and it is therefore unnecessary to inflict on the patients the inconvenience of tight bandages. As the consequent shortening of the bone does not materially interfere with the functions of the limb, a good cure may be obtained by wearing for a few days the arm slung in a handkerchief, and afterwards by the application of a starch-bandage around the chest, the hand of the injured side reposing on the opposite shoulder.

Six cases of fracture of the arm were admitted into the wards, With regard to injuries of the shaft of the humerus, M. Velpeau remarks that they are especially liable to non-consolidation, on account of the facility of displacement, the bone being thickly covered with muscles, and isolated between movable joints, such as the shoulder and elbow, which readily impart slight movements to the fragments. These fractures should therefore be closely watched.

The mode of treatment formerly adopted in fractures of the lower extremity of the radius frequently induced protracted loss of power of the hand. Those who have witnessed the effects of Dupuytren's bent split are aware that incomplete ankylosis of the wrist was often the consequence. Nothing of the kind now occurs, thanks to a mode of reduction, the invention of which M. Velpeau ascribes to a Danish surgeon; this plan, slightly modified, yields excellent results.

M. Velpeau effects reduction by grasping and powerfully extending the hand, placed in a prone position, and bent at right angles on the fore arm. The flexor tendons are thus brought to bear on the displaced fragments, and facilitate reduction. The limb is then secured in this position with a roller; a padded compress is laid along the extensor side of the forearm and hand; wet pasteboard splints are applied on the anterior and on the posterior aspects of the limb; and a starch-bandage is rolled over all. During the desiccation of the starch, the surgeon should carefully watch the hand, and prevent it straightening, which can easily be done by provisionlly fixing it with tape-ribbons.

This apparatus was used in the ten cases of fracture of the lower extremity of the radius noted in M. Velpeau's returns, and the use of the hand and fingers were, in every instance, restored in less than two months.

A case of fracture of the olecranon suggested to the Professor a parallel between this bone and the patella, and he remarked that ligamentous union of the fragments was perfectly sufficient to secure the restoration of the functions of the limb; and therefore, instead of using a system of tight bandaging liable to induce mortification, he conceives it sufficient to apply merely a figure 8 roller, and in a month or six weeks a satisfactory result is attained.

With regard to dislocations, we may confine ourselves to the statement that, eight cases of a simple character were observed—viz., six luxations of the shoulder, and two of the elbow.

Seventeen cases of sprain are recorded, in all of which the treatment resorted to consisted in entire repose and resolutive dressings. M. Velpeau is not systematically opposed to the use of shampooing in these injuries, but he protests against the incautious and indiscriminate application of the method by ignorant quacks.

Forty-five cases of arthritis were treated with success by antiphlogistic measures, extensive blisters, and especially by immobility of the joints, which is more certainly obtained by the use of the dextrine or starch bandage than by the most ingeniously devised mechanical apparatus.

In nine instances of hydarthrosis the innocuity and advantages of the iodine injections were again fully displayed.

In thirteen cases of disease of serous bursæ, and tendinous sheaths, Mr. Velpeau resorted to incision in the acute stage, and to the iodine injection in the chronic period. M. Velpeau unhesitatingly recommends the injection even when the bursæ are in communication with a joint.

Seven cases of anthrax, and two of extensive carbuncle were relieved by deep radiated incisions. Anthrax is a formidable affection, the progress of which can be arrested but by a liberal use of the knife.

M. Velpeau's return contains no less than 135 cases of phlegmonous inflammation of the cellular layer, which assumes a different aspect in the various parts of the body according to the density of the structures involved. In compact and closely-connected tissue inflammatory action progresses slowly and is confined within narrow limits, but in looser textures it spreads so rapidly that when four days have elapsed, neither pressure nor local applications can be expected to afford any satisfactory results, and extensive incisions only can check the disease. In the palm of the hand the synovial grooves greatly add to the dangers of inflammation, and when it arises beneath the callosities occasionally observed at the base of the fingers, the irritation displays a tendency to spread to the dorsal aspect of the hand, where it meets with looser tissues, and the incision should always be performed in the palm of the hand.

The Professor presented interesting remarks on inflammation of the lymphatics. Thirteen instances of *Angioleucitis* were observed, two of the patients only being women. The affection is especially formidable because it promotes the development of other forms of disease. It arises in ulceration of the skin, but deep-seated affections doubtless occasion in the lymphatic vessels disturbances, the intimate nature of which escapes the observer, and might perhaps afford an explanation for many obscure pains. Angioleucitis should be carefully distinguished from phlegmon and phlebitis, and more especially from erysipelas, which is more dangerous to life, and an affection in which the entire system obviously participates. Erysipelas sometimes does not arise from any local injury, and extends in all directions, away from its original seat, never induces suppuration, and follows its course regardless of every effort of treatment; angioleucitis, on the contrary, invariably has its origin in one spot, which it never altogether abandons, even when it has invaded the glands, often causes suppuration, and in almost every instance yields to depletion, blisters and local remedies. Cellulo-cutaneous phlegmon spreads around a central spot, runs rapidly to suppuration, and induces mortification of the cellular tissue; angioleucitis extends in patches, suppurates slowly, and yields a scanty puriform secretion. In addition, it can readily be discriminated from phlebitis, which can be felt but is not seen, whereas angioleucitis is more easily seen than felt.—JUST LUCAS CHAMPIONIERE.

THORACENTESIS.

The question of Thoracentesis is still being discussed at the Academy of Medicine, where the voice of M. Beau will no longer be heard. We may therefore be permitted briefly to reproduce the late Professor's remarks on a case of pleuritic effusion which occurred last year in his wards.

The patient was a woman, a native of Brittany, of mature years, and, like her country people, very obstinate. When admitted into hospital, she presented the symptoms of effusion in the *left* side of the chest. We purposely italicise the word, because the effusion was as complete as possible, and because it is on that side that the morbid secretion is usually

and so copious as to fill the cavity of the pleura. The spnœa was extremely intense, and as every means of treatent, save thoracentesis, had already been resorted to, that eration was decided on at once, and was performed accordg to the rules laid down by Reybard.

The division of the skin with a lancet previously to the ertion of a trochar is, to say the least, unnecessary. In ne cases the excessive distension of the walls of the chest œdema of the parietes, resulting from the protracted eral recumbent posture, renders the discovery of the ercostal spaces somewhat difficult, and may cause some barrassment to the operator. All doubt, however, can dily be removed by a very simple plan resorted to by M. au. Depressing with the left forefinger one of the intertal spaces, he marked with the edges of the finger the pective situation of the superior and inferior ribs, and s ascertained that the axis of the finger corresponded cisely with the central line of the interval between the . He then drew back the skin, in order that the superal and deep-seated apertures might not directly corresd, and boldly inserted the trochar into the chest in front the middle part of the nail, thus averting all chance of blade striking against the bone instead of penetrating the cavity, and also the risk of injuring an artery or of nitting air into the chest.

After the withdrawal of the blade, the fluid flows through canula in varying quantities; the surgeon must not ext to be able to remove it to the last drop, which, more-r, is unnecessary. M. Beau once effected a cure in a in which only a few ounces escaped; sometimes, on contrary, large quantities of liquid are drawn off. By ans of thoracentesis (said the Professor), a kind of *post-tem* examination is made in a living subject. The liquid tained in the pleura is not merely serous, but sero-fibrin-, and, on cooling, deposits a considerable amount of in, a fact which implies and demonstrates its inflammaorigin.

n some instances the fluid escapes freely, and the immee object of the operation is attained, but in others, e or no liquid flows from the canula; a circumstance of isappointing nature, and due to the presence of false nbranes instead of a fluid secretion in the chest. It is y desirable to avoid this occurrence, which it would be air to impute to want of skill in the operator. To guard inst the contingency alluded to, M. Beau trusted to the wing stethoscopic signs:—When absolute absence of nance on percussion coincided with distinct tubar respion, he considered the existence of a liquid secretion in the pleura as clearly demonstrated; a fact which in y instances he was enabled to test by the immediate rn of vesicular murmur after the performance of thoraesis. He thus acquired the conviction that the souffle eurisy is always referrible to the presence of a fluid in the thorax; when, on the contrary, no tubar or chial souffle is audible, he conceived it equally certain the secretion was chiefly pseudo-membranous, and but little liquid would escape from the canula. Some-s a semi-solid pus oozed from the tube; and therefore bsence of bronchial souffle should not absolutely deter urgeon from the operation, but in such cases he should the precaution of mentioning beforehand the probable t of the puncture.

he possibility of penetrating into the abdomen through liaphragm has been alluded to. If any doubt exists as e spot in which the aperture should be made, it is a practice to puncture the chest high up, more especially is now conceded that the removal of the whole of the d is not imperatively required.

he operation should not be instituted only as a curative ure. Thoracentesis is easily performed, and when cauly resorted to is attended with little peril; in addition, eviates the sufferings of patients who otherwise must ptly perish. It should, therefore, be viewed as a valuable tive, and as the procedure sometimes effects a cure, is ctly unobjectionable.

is not easy to explain the curative action of thoracenit would seem that after the puncture, the vacuum formed in the pleura should have a tendency to promote a fresh accumulation of morbid secretion; a relapse is indeed occasionally observed, but not invariably, and the patient often recovers. In this case, the secretive power of the membrane is, in all probability, exhausted.

If after an interval of a few days the extent of the dulness on percussion does not increase, a favourable issue may legitimately be expected. But if dyspnœa recurs, together with increased dulness of sound, the case will almost always prove fatal. M. Beau has never observed an instance of recovery from acute pleurisy with effusion, when it was necessary to repeat the operation. At Hospital Cochin, thoracentesis was five times repeated in the same subject, at his own urgent request; a fact which shows that the procedure is not in itself very formidable to the patient. The two first operations yielded a fluid which promptly coagulated: when the chest was tapped for the third time, serum escaped at first, and subsequently pus, but no fibrinous matter; hence it would seem that the latter had supplied the materials of the purulent secretion, and that such is the mode of transformation of these varieties of interminable pleurisy.

In the case which suggested the present remarks, a small amount of tubar respiration was audible; the puncture was performed in the manner we have described, and gave issue to a large amount of fluid. The patient was doing well, and sanguine hopes of her recovery were entertained, when, in spite of every remonstrance, she went into the garden and took cold; a relapse followed, with fatal results.

We may, however, infer from the above remarks, that if M. Beau's precepts are not departed from,—Firstly, the operation may be performed with entire safety; secondly, that it is possible easily to foresee its immediate results; and, thirdly, also to ascertain with equal facility after a few days' interval what will be its ultimate consequences.—Just. Lucas Championniere.

Good Effects of Veratria in Rheumatic Fever.

Rheumatic affections, unconnected with scarlatina, have of late, extensively prevailed in Paris among young children. The disease observed has chiefly been simple rheumatic fever, precisely similar to that which occurs in adults, and liable to the same complications. In ten cases of the kind admitted into M. Bouchut's wards at the Hospital for Infancy, the rheumatic affection was aggravated by the coincidence of pneumonia, pleurisy, endocarditis, and more frequently pericarditis.

M. Bouchut adverted especially to the case of a child aged eight years, who, when conveyed to the hospital, was suffering from fever and rheumatic pains in the ankles, and who, after an interval of a few days, became affected with pneumonia of the left lung, and subsequently pericarditis, with much præcordial bulging, and increased dulness on percussion in the cardiac region. Death followed, and on dissection the lung was found in a state of hepatisation; and on either side pleurisy was present. The valvular structures of the heart were thickened, and the pericardium contained a large amount of liquid and of false membranes.

During life it is often more difficult to ascertain the presence of endocarditis than that of pericarditis, the signs of which render the characteristics of the former more obscure. It is nevertheless of frequent occurrence, and a well-marked instance was observed in M. Bouchut's wards in January, 1865. The patient was a lad of fourteen, who had suffered from exposure to a storm of rain and snow. Two days afterwards, oppressive dyspnœa supervened, together with much præcordial pain, palpitation, swelling of the face, and œdema of the feet, hands, and scrotum, but without albuminuria. The dulness over the region of the heart did not exceed two square inches; the sounds of the organ were remote and indistinct, &c. Those symptoms were promptly relieved by cupping, and were followed by the development of no organic disease.

With regard to myocarditis, which M. Bouchut views as a necessary consequence of the existence of endo-pericarditis, the Professor remarked that the great irregularity of the action of the heart is in all probability the result of spasmodic action of the viscus, occasioned by a rheumatic condition of its muscular fibres.

Active treatment is required in rheumatic fever occurring in infancy, on account of the possible contingency of subsequent disease of the heart or other important organs. Depletion, however, should, if possible, be avoided in lymphatic subjects, and this quinine and veratria supply us with the means of doing.

M. Bouchut prefers the latter drug, because sulphate of quinine not unfrequently induces vertigo and permanent injury to the organs of sight and hearing, and because veratria is an inexpensive medicine.

We described, three years ago, the mode of administration of this substance, which is still adopted by M. Bouchut. He prescribes:

℞ Extr. opii, Veratriæ, } ā gr. j.

Divide into twelve pills, silvered, each containing one-tenth of a grain of the active ingredient. Two pills are exhibited on the first day, three on the second, four on the third, and so on, as far as seven at most in the course of the day. Anodyne enemas are administered each morning in order to relieve the bowels, and prevent colic and diarrhœa. If vomiting supervenes, the medicine should be discontinued.

The feverishness, in general, very promptly yields to this treatment, the pains subside, and convalescence soon sets in. M. Bouchut has never noted any ill-effects whatever from the use of this valuable remedy.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows, held on Oct. 23rd, the following Member of the College was duly admitted a Fellow of the same;—Benjamin Ward Richardson, M.D. St. Andrews, Hinde-street, Manchester-square.

At the same meeting, the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practice Physic as Licentiates of the College:—Alexander Bruce, Albert Terrace; Frederick John Burge, junior.' Marlborough Villas, New-road' Hammersmith; George Gregory, Moses-gate, Bolton; Henry William Larking, Bilston; Richard John Lupton, Stanhope-street, Hampstead-road; James Grosvenor Mackinlay, Isleworth, Middlesex; Thomas Hall Redwood, L.M. Durham, Rhymney; George Henry Savage, Doddington-grove, Kennington; Richard Burford Searle, St. Just, Cornwall; Charles Smith, Richmond-street, St. George's road, Southwark; Francis Thomas Tayler, Brunswick-place, Lewisham-road, New Cross; Alfred Edward Wilmot, Nelson-square, Blackfriars-road.

The following were reported by the Examiners to have passed their Primary Examination for the Licence of the College:—William Edmund Cant, St. George's Hospital; Louis Marc Le Grand, University College; Augustin Le Rossignol, Stratford, Essex; William F. B. Pollard, King's College; W. Wilberforce Smith, Middlesex Hospital, Frederick W. Young, University College.

A SUCCESSFUL CASE OF OVARIOTOMY IN PARIS.—M. Labbé introduced to the notice of the Academy of Medicine a patient twenty-nine years of age, on whom he had performed ovariotomy three months before. Suffering from pains and enlargement of the abdomen for seven or eight years, the tumour had only began to assume a large size eight months prior to the operation, the cyst on its extraction containing twenty-one kilogrammes of liquid. The operation was performed, with M. Gosselin's assistance, at a *maison de santé* situate in a large garden. The contents of the multilocular cyst were gelatinous, but there being no adhesions the removal was easily accomplished with the aid of Mutthieu's clamp, the "*toilette du péritoine*" being most carefully performed by means of fine new sponges. Thirteen points of twisted metallic suture were applied, the peritoneum being included in the suture,—a point to which M. Labbé attaches great importance as a means of preventing the purulent fluids issuing during the healing of the wound gaining access to the peritoneum. The operation was performed slowly, lasting "seven quarters of an hour," the patient being under the influence of chloroform. It was executed on the 19th of July, the patient being able to walk on the 10th of August, and she was presented to the Academy on the 17th of October.

A DISGUSTING EXHIBITION IN DUBLIN.—We have been honoured with a special invitation to inspect the person of an individual named Jean Baptista dos Santos, who is desirous of turning a disgusting malformation, of which he is the subject, to financial account. We have not availed ourselves of the complimentary card lest we should be assumed by our presence to imply approbation or gratification at the publication of such obscene details, but we have seen a photograph of the deformity—a sufficiently disgusting *exposé* without the display of the original. The deformity is, as far as we could see, completely devoid of scientific interest, and unworthy of any more exalted interest than morbid curiosity for such filthy displays. In any case, no other motive can attract the non-professional visitors whom dos Santos invites to pay their money, and we hope few will be found to do so. It is an abominable abuse that the "Private Levees for Gentlemen only" of this person should stare the public, who want to know nothing of his disgusting deficiences or redundancies, on every dead wall in Dublin, and it would be better for the victim of such affliction to regard them as a something to be ashamed of instead of placarding his disgusting degradations.—'Medical Press.'

SUPERVISION OF EXAMINATIONS.—The English Branch Council has practically acted upon the resolution of the last general meeting of the Medical Council as to visitation of examinations by appointing visitors to the English licensing bodies. The resolution adopted is, that the President and Dr. Alderson be deputed to visit the examinations held by the University of London; that Dr. Sharpey, Mr. Cooper, and Dr. Parkes be deputed to visit the examinations held by the Royal College of Surgeons of England; that Dr. Parkes, Dr. Quain, and Mr. Rumsey be deputed to visit the examinations held by the Society of Apothecaries of London; that Dr. Paget and Dr. Quain be deputed to visit the examinations held by the University of Oxford; that Dr. Acland and Dr. Embleton be deputed to visit the examinations held by the University of Cambridge; and that Dr. Storrar and Mr. Cæsar Hawkins be deputed to visit the examinations held by the Royal College of Physicians of London. No examinations will be held for the University of Durham before June, 1866, and therefore no visitors have been appointed.

ROYAL COLLEGE OF SURGEONS.—At a special meeting of the Council, on the 26th inst., convened for electing two members of the Court of Examiners in the vacancies occasioned by the resignation of Mr. Joseph Hodgson, F.R.S., and of Mr. F. C. Skey, F.R.S., whose term of office had expired, Mr. Frederick Carpenter Skey, F.R.S., of St. Bartholomew's Hospital, was re-elected, and Mr. Richard Quain, F.R.S., University College Hospital, was elected examiner for the next five years, in the vacancy occasioned by the resignation of Mr. Hodgson, who still retains his seat at the Council table. At the same meeting of the Council, Mr. William Anthony Harrison, of Keppel street, Russell square, a Fellow of the College, was elected a member of the Dental Board, in the vacancy occasioned by the resignation of Mr. Thomas Bell, F.R.S.

YELLOW FEVER AT SWANSEA.—The disease has entirely disappeared from the town, which is at present in an unusually healthy state.

A SUCCESSFUL CASE OF OVARIOTOMY IN FRANCE.—M. Labbé, a hospital surgeon of Paris, presented (Oct. 17th) to the members of the Surgical Society, a woman, aged twenty-nine, in a perfect state of health, upon whom he had performed ovariotomy three months before.

WE have to record the death of three Medical gentlemen well known to the Profession—Prof. Alquié, highly respected, at Montpellier; Prof. Remak (whose microscopic researches have been so valuable), at Kissingen, of anthrax; and Prof. Cerioli, at Cremona, at the advanced age of eighty-four.

BEQUEST.—The late Mr. Nathaniel Soames, of Warwick ardens, Kensington, has just bequeathed 10,000*l.* to the llowing metropolitan hospitals :—2,000*l.* to the West ondon, at Hammersmith ; 4,000*l.* to the Great Northern ledonian road ; and 4,000*l.* to the North Lonndo Hospital ower street.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At a eeting held on the 18th ult., the following office-bearers re elected for the ensuing year :—President : Dr. James nsmure. Secretary : Dr. James Simson. Treasurer : John Gairdner. Librarian : Dr. Archibald Inglis. sident's Council : Drs. James S. Combe, Andrew Wood, bert Omond, Benjamin Bell, James D. Gillespie, Mr. nes Spence, and Dr. John Gairdner, *ex. off.* Examiners : s. James Simpson, Richard Huie, William Dumbreck, chibald Inglis, Andrew Wood, Robert Omond, James nsmure, Peter D. Handyside, James D. Gillespie, Henry Littlejohn, Patrick H. Watson, and David Wilson. essors to Examiners : Dr. James S. Combe, Messrs. les Syme, William Brown, and James Spence. Con- ator of Museum and Register of Students' Tickets : William R. Sanders. Officer : Mr. John Dickie.

EDICAL VICTIMS TO THE CHOLERA.—M. Cacciaguerra, edical student attached to the St. Antoine Hospital, of s, caught the disease whilst attending cholera patients, died very rapidly. Several other students are lying tricken by the epidemic. We learn that M. Mocquot, of these excellent young men, has just died. The wing medical practitioners have recently died at na whilst attending cholera patients. We find the n the 'Imparziale,' of Florence ; and hope, with the r, that the Italian Government will not forget the ws and orphans. In fact, nothing less than great ality towards the relicts and the children can be ted by the medical body as a recognition of the sm of these men, Drs. Jacobi, Persichelti, Stefanini, oli, Marchetti, Piccinini, Polloni, Corbisier, Pederzolli, onetti.

ESENTATION.—Mr. Hartley, a well-known and highly- ned Surgeon, who has practised for the last twenty at Ivybridge, Devon, and who has lately left that has been presented by 170 of the principal inhabi- of Ivybridge and its neighbourhood with a handsome ionial in the shape of a valuable silver salver. The ionial was presented at a meeting presided over by the bent of Ivybridge. The salver bears the following tion :—" Presented to Mr. and Mrs. E. Hartley, as a of the esteem and regard in which they have been y their numerous friends during a residence of nearly years in Ivybridge ; to the former for his valuable mpt services rendered in time of need, particularly poor ; and to the latter for her sympathy in affliction fulness in every good and Christian work.—Oct. 21,

CAL VISITORS TO LICENSED LUNATIC ASYLUMS.— late Wilts and Gloucester Quarter Sessions it was l, that if any Medical visitor were, by order of the required to make extra visits to the licensed Luna- um, he should be remunerated for the same beyond fixed for his ordinary attendance as Medical visitor.

CHOLERA IN PARIS.—During the last week the has been on the increase in Paris, and has exceeded idable number of 300 deaths per diem, reckoning ind hospital patients. While at some hospitals a on in the number of admissions has been observed ; these have increased, so that the St. Antoine and ité now receive more than the Hôtel-Dieu ; but it is e practice that the increase is chiefly observed ; ny of the patients who were already in the various for other complaints prior to the outbreak have tims to it. It has been noted that of 210 deaths ; in a certain quarter of the town, 90 of the indivi- upied the *rez de chaussée* (ground-floor), 43 of this eing *concierges* (door-porters), and the remainder fruiterers, charcoal sellers, &c., pointing with evi- onstration to the effects of an insufficient supply of efective ventilation. According to a communica- tion of M. Guyot, one in three of the patients received at the Hôtel-Dieu and the Lariboisière recover, some of the cases having reached a very advanced stage on their recep- tion. At both these Hospitals a favourite tisane for the purpose of inducing reaction is the rum tea, 125 parts of rum to 875 of tea, the *elixir de la Chartreuse* being also given with success. When there is much vomiting, ipecac. in doses of from ten to thirty grains is also given, and bis- muth when the diarrhœa is persistent.—'Medical Times and Gazette.'

ROYAL PRESENT OF PLAYTHINGS FOR SICK CHILDREN. —The little patients under treatment in the Hospital for Sick Children in Great Ormond street, have again been the objects of Her Majesty's kind and thoughtful regard. The hearts of these suffering little ones were last week gladdened by another present of toys from the Queen. A large pack- ing-case full of articles selected by Her Majesty as suitable for distribution among the children arrived from Coburg. These toys are given to the patients, who highly prize them, and carry them away when they leave the hospital. Num- berless small mementos of Royal consideration thus find their way into some of the holes and corners of the poor in London and the country, as this hospital receives patients from all parts of the land.

THE CATTLE DISEASE.—We have been informed, says the 'British Medical Journal,' on good authority, that the number of cattle that have died in this country of the rinderpest does not exceed 1,700 up to the present time. Not a single sheep has yet been reported as killed by the disease. The rise in the price of butcher's meat is, there- fore, in no way fairly attributable to the destruction by dis- ease of animal life.

DEATH OF PROFESSOR MALGAIGNE.—This eminent sur- geon died a few days since, at Paris, of cerebral apoplexy. This was the third attack, and for the last six months he had been unable to attend to any of his duties. It will be recollected that M. Malgaigne was first seized about nine months ago, when presiding over the Academy of Medicine of Paris, of which for many years he had been one of the most eloquent members. The deceased was of humble origin, and had reached the highest position by his natural gifts and indo- mitable industry. His edition of Ambrose Paré, his Opera- tive Surgery, and his treatise on Fractures and Luxations, are known to surgeons of all countries. Prof. Malgaigne was accompanied to the grave by deputations of the Medical Institutions of which he as a member ; and talented as well touching discourses were delivered on the occasion. Among these we should single out M. Velpeau's, which is a model of oratory.—'Lancet.'

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, Nov. 1.—*Operations* at Middlesex Hospital, 1 p.m. ; St. Mary's Hospital, 1½ p.m. ; St. Bartholomew's Hospital, 1½ p.m. ; Great Northern Hospital, 2 p.m. ; University College Hospital, 2 p.m. ; London Hospital, 2 p.m. ; Obstetrical Society.—Dr. Marion Sims, "On Prodicentia Uteri ;" Mr. Roper, "On Embryotomy," and other papers.

THURSDAY, Nov. 2.—*Operations* at the Central London Oph- thalmic Hospital, 1 p.m. ; St. George's Hospital, 1 p.m. ; London Surgical Home, 2 p.m. ; West London Hospital, 2 p.m. ; Royal Orthopædic Hospital, 2 p.m. ; Harveian Society, 8 p.m.—Dr. Tilbury Fox, "Remarks on the Cholera in Egypt" King's College Medical Society.—Mr. Herbert, "On Smells in Relation to Disease."

FRIDAY, Nov. 3.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m. ; Western Medical and Surgical Society of London, 8 p.m.—Practical Evening for the Narration of Cases and the Exhibition of Specimens."

SATURDAY, Nov. 4.—*Operations* at St. Thomas's Hospital, 1 p.m. ; St. Bartholomew's Hospital, 1½ p.m. ; King's College Hospital, 1½ p.m. ; Royal Free Hospital, 1½ p.m. ; Charing- Cross Hospital, 2 p.m.

MONDAY, Nov. 6.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m, ; Metro- politan Free Hospital, 2 p.m.

TUESDAY, Nov. 7.—*Operations* at Guy's Hospital, 1½ p.m. ; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Photographs of Diseases of the Skin. By B. Squire, M.B. Class IX.: Maculæ. London: John Churchill and Sons, New Burlington street.

The Antecedents of Cancer. By C. H. Moore, F.R.C.S. London: T. Richards, 37 Great Queen street.

Epileptics: their Mental Condition. By W. A. F. Browne. London: J. E. Adlard, Bartholomew Close.

Report on the Sanitary Condition of the City of London for the Quarter ending Sept. 1865. By H. Letheby, M.B., &c. London: M. Lownds, Fenchurch street.

On Epidemic Cholera and Diarrhœa; their Prevention and Treatment by Sulphur. By John Grove, M.D., &c. Third Edition. London: R. Hardwicke, 192 Piccadilly.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

To SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

THE TREATMENT OF ESCHARS FROM BURNS.

To the Editor of the Medical Circular.

SIR,—Take ung. hydr. nitrico.-oxydi., ung. zinci., ung. flor. sambucæ., of each two drachms; when well incorporated, add liq. plumbi. diacetatis, ℥xxv. This is to be mixed by raising the mass up by the end of the spatula, and stirring it after the manner of making yeast dumplings. This ointment is to be applied thickly by the spatula or finger on to the eschars, and perfectly excluding them from sight. Place on this a piece of gutta-percha, and over it about two or three thicknesses of lint which have been well saturated in cold water. Bind them up and let each remain for twelve, eighteen, or twenty-four hours. The rationale is this:—Exosmosis takes place under the eschar, and the ointment finds its way there. When the dressing is removed, and the eschar found to be loose enough, remove it entirely; but if it still adheres too tightly repeat the process. When the eschar is removed apply the ointment again, but instead of the gutta-percha put on the lint well wetted as before. In the first place, the gutta-percha prevents any ointment being removed from the eschar; and in the second, the wetted lint absorbs it only partially. These eschars should only be dressed once in twenty-four hours, and the *golden rule attended to of never allowing them to form again.* Both eschars will yield to this treatment, but will leave their indelible white marks when healed, owing to the total destruction of the cellular tissue beneath them. The same treatment is applicable to all this class; of rupia, scabies, eschars, and many forms of the porrigo and scalp diseases. The great philosophy of the treatment is their speedy removal, and never allowing them to scab again, which they cannot do if proper care is taken under the process above stated. "LAMBDA" should publish the result.

I am, &c., "CYCLOPS."

THE OBSTETRICAL SOCIETY.—The notice has been received.

THE HARVEIAN SOCIETY.—The card has been received.

ST. PETER'S HOSPITAL.—The notice has been received.

MR. N. C.—We cannot at present give a decided opinion upon the value of hypodermic injections, as the subject is now undergoing investigation at the hands of a committee of competent observers, and their report will materially affect the decision arrived at by the Profession.

DR. T.—The paper has not yet reached us.

AGATHOS.—We received the newspaper, but as there was no mark to indicate the passages to which it was intended to direct our attention, we were unable to make use of the information.

G. N. (Sheffield.)—The gentleman in question was in practice before the year 1815.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ½ oz., 3s. 4d.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 78 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments, forwarded for 6 stamps

Brass and Zinc Door-Plates.—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges. Chemists' Shops fitted up with Window-sill Plates in the plain or O.G. Patterns. Lists of Prices post free.

Plates altered and repaired.—Country orders punctually attended to.

36 CHANDOS STREET, CHARING CROSS, W.C.

Treloar's Kamptulicon,

COCOA-NUT MATTING,

AND OTHER DURABLE FLOOR COVERINGS,

67 LUDGATE HILL, LONDON,

Three doors from the Railway Bridge.

William Hawke, Wild Court, Great WILD ST., DRURY LANE, LONDON W.C., (late Ansell and Hawke), Manufacturer of every description of Shop Fittings, Dealer in Medical Glass, Earthenware, and all kinds of Shop Utensils, Medical Labelling, Writing, and Embossing on Glass.

Drawings, Specifications, and Estimates furnished for Fitting-up Druggists' Shops and Surgeries with every requisite, and for erecting Shop-fronts. Druggists' Stocks and Fixtures valued.

Medical Fixtures and Glass Manufactory, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Altering in the above Profession, that he has an extensive assortment of SHOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc

H. Silverlock's Medical Label Warehouse, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctor's Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.

YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.

SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.

LABEL CASES for the use of Surgeons, 14s., 18s., and 24s.

LATIN SLIP LABELS for Wholesale Druggists.

Catalogues sent on application.

Geo. Smith and Co.'s Pure Extract of CALVES' FEET for INVALIDS and CULINARY USE. Sold in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Druggists, Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland street, Regent street Office: 94 Upper Thames street, E.C.

The Medical Circular.

OPENING OF THE DUBLIN SCHOOLS OF MEDICINE.

The Introductory Address to the Medical Session of the ater Misericordiæ Hospital was delivered Oct. 31st, in the cture hall of the hospital, by Francis Richard Cruise, Esq., D.

Dr. Cruise proceeded to deliver his Inaugural Address as llows:—I have been requested to address a few words to e hospital class upon the occasion of opening the coming ssion—the fifth in the history of the Mater Misericordiæ ospital. The great importance and boundless extent of e subject upon which I am expected to address you con- itute difficulties almost insurmountable to any one, and ubly so to me, whose lack of years and scanty experience ve afforded but little opportunity for reflection, either for y own guidance or for the direction of others. Compelled I am to select from the vast field before me a theme for is morning's discourse, I have resolved to address myself the few minutes at my disposal to the junior portion of y audience. For their especial benefit I shall endeavour draw, in all truthfulness, a brief sketch of the profession ey are about to adopt—to portray, so far as my own preciations enable me, its difficulties, its attractions, its als and penalties, its pleasures and rewards. I shall, reover, so far as lies in my power, indicate those means ereby it may best be learned, and the errors to be avoided its pursuit. If in this attempt I shall prove fortunate ugh to assist any one of my young student friends, in furtherance and successful attainment of the grand un- taking before him, I shall consider myself amply recom- ased, even for my temerity in trespassing upon the valued ie of those distinguished and respected hearers by whom m surrounded. On the threshold, let me remind you, ing gentlemen, that, although placed here as a lecturer, n no less a student than the youngest present; that the advantage I can be supposed to enjoy over you is the erience of a few years, devoted to the study you are now oaching; the utmost gain you can reap from my words; w hints to guide your first labours in the profession of choice. I believe that I may take it for granted that first and most indispensable requisite for success in any rtaking to which we may devote ourselves is to com- e with a thorough comprehension of its nature and t. This enables and inclines us to fix the attention the more essential points, and guards the mind from ting hither and thither with every passing distrac-

I shall, therefore, commence this morning's ad- with a short exposition of the nature and objects ie study of Medicine. Taken in its most ex- d signification, this study includes all the various hes of human knowledge which, united, enable us to nise the countless forms of morbid action that menace estruction of organised life—which instruct us to pre- nd understand the course and final termination of those an phases of evil—and which arm us to protect, to and to comfort suffering nature in the combat with myriad ills which descend as heirlooms to her fallen

A brief reflection analyses these motley elements of ledge into three leading groups in accordance with final purposes—namely, first, those which qualify for cognition of abnormal conditions, or for what is tech- y termed diagnosis; secondly, those which appertain nature and history of morbid states, or pathology; y, those which instruct us to avert, so far as may be le, the impending evils of disease, or therapeutics. ing this analysis to the most practical application pos- et us reflect for a moment upon the three grand ques- tions, which the physician must answer whenever he stands by the bed of sickness:—first, what is the disease? secondly, how will it result if left alone? thirdly, what assistance can be rendered, and how?—I shall endeavour to point out as succinctly as possible the means whereby you may attain the grand end of answering these questions with justified confidence. In the first place, as regards diagnosis, if you would acquire the power of accurately recognising disease, you must, in the commencement, gentlemen, devote yourselves to the investigation of the structure and functions of the human body in health, and then to their contemplation in disease. In a word, you must begin with the study of anatomy and physiology, and subsequently pass on to that of pathology. Anatomy and physiology claim our first attention, inasmuch as they constitute the foundation of all Medical science. The truth of this statement scarcely needs illustration. In order to ascertain the seat and nature of any defect which may befal a complex piece of mechanism, it is necessary to be acquainted with the structure, relative position, and use of all its constituent parts. The human body is the complicated and delicate machine, to cure whose derangements the physician's aid is sought; and the first and most essential qualification on his part is a full knowledge of the wondrous fabric in all its minutest details. Without this he is unable to recognise the situation, amount, or nature of the disorder. To learn anatomy then, gentlemen, is the first portion of the great task which awaits you. I shall endeavour to place before you the means by which this can be accomplished. Not to dishearten, but, rather for the purpose of stimulating you to early and strenuous exertion in this department of your studies, I may premise that the work is one of great difficulty. Begin it, then, forthwith, and follow it up with perseverance and method. Commence by learning, with the aid of your manuals and of a set of bones, the anatomy of the human skeleton; thence pass on systematically through the ligaments, joints, muscles, vascular systems, brain, nerves, and viscera; study them over and over, day and night, until you have stored your memory with a good general knowledge of the subject. It is a much disputed point whether anatomical plates are serviceable to the pupil or not. I have no hesitation in stating my conviction of their great advantage, when properly used. They are no substitute for dissection, but in a course of anatomical reading I believe them to be invaluable in guiding the student and rescuing him from almost overwhelming and inextricable confusion. At the same time, attend the lectures and demonstrations, noting what you see and hear; occupy a portion of your evenings in writing out these notes, correcting and condensing them; finally, endeavour, either alone or with the assistance of others, to reduce your knowledge to the form of question and answer. This conveys quickness of thought, and facility of expression—affords opportunities for the removal of misconceptions, and the elucidations of obscure points. A system, such as I now lay down, will prepare you to dissect with ease and advantage, and will save you from the heavy, discouraging task of groping after parts whose name, position, course, and relations, are alike new and unknown. I am fully aware that many censure resort to the artificial aid I now suggest, maintaining that dissection alone is the means to proficiency. I admit the statement, and would merely qualify it by reiterating my conviction, derived from experience and observation, that, to dissect to good purpose, the student must be prepared beforehand by a course similar to that I recommend. On such a foundation let him rear the superstructure of practical anatomical facility, acquired by repeated investigation of every portion of the human body. Let him see and feel, separately, and in all their relations, every part of which he has read. This will give him habits of precision and certainty in this all-important science, like unto that of the practised musician whose fingers, almost unconsciously to himself, fall upon the notes he seeks. On the subject of *Dissection*, I can scarcely speak with adequate emphasis. This is the focus to which all your previous exertions must converge. To suit youselves for it, is the end and object of the laborious preparation I have advised. It is the solitary means whereby a useful knowledge can be

obtained, the only school in which dexterity and certainty in operation can possibly be acquired. Practice it incessantly; sacrifice everything for it, save hospital attendance. If you are juniors, seek the assistance of those more advanced; if you are seniors, dissect for those who are beginning. Be convinced that every hour so spent will abundantly repay you in the fulness of time. To learn anatomy is unquestionably a stupendous work; yet it is far from impossible; there is no obstacle which perseverance cannot surmount. After a little patient attention, the obscurity and perplexity which at first render it so unattractive, clears away and reveal to contemplation a science which, of itself, would amply repay the time and labour expended, even were it not, as we consider it to-day, a means to the grander end of aiding the physician to heal. Great and ever-increasing must be your gratification as you unravel the marvels of God's power and goodness in the structure of his last, most perfect creation. Still greater pleasure awaits you when a knowledge of physiology is superadded to your store, enabling you to interpret the wonders of construction by their exquisite adaptations to function. To dilate upon this subject would occupy us interminably. Time forbids that I should even briefly allude to the numberless illustrations I might select:—to the ear, as an acoustic instrument, so admirably contrived to gather and convey to the centre of sensation the faintest vibrations of the atmosphere—to the eye as a masterpiece of optical construction—to the arm, elbow-joint, hand, as the perfection of mechanism. Nay, were I even to analyse my present act of speech, I could scarcely within an hour trace and describe its phenomena. Therefore, we must needs pass on to other matters bearing more closely upon the subject of this morning's discourse. Viewing anatomy solely in relation to Medicine, we find it occupying a place sufficiently important to render it worthy of all the labour it demands. We have already seen how and why it forms the groundwork of all Medical knowledge, and it is scarcely necessary for me to illustrate here its constant relation to the practice of our art. Without a perfect acquaintance with the skeleton, no surgeon can recognise the various forms of fracture. Unless he intimately knows the structure and movements of the joints, dislocations may be overlooked, and left unreduced—monuments to his disgrace—life-long reproaches to his ignorance. Without a knowledge of the muscles, the various displacements which occur in fractures and luxations cannot be understood or remedied. To anticipate and explain the course of abscesses, aneurisms, and other tumours, the fasciæ in all their inflexions must be traced. A minute knowledge of the nervous system is the only key to unravel the perplexity of symptoms, more especially in what is commonly termed Medical disease. Of the vital importance of a knowledge of the vascular system, we have incessant proof, and that knowledge must be perfect and ready at all times. Which of us can foretel the hour when we may be summoned to a case of hæmorrhage, the life of a fellow-creature depending on the rapidity with which a ligature is cast around the bleeding vessel—all this, moreover, without one moment of time to obtain assistance, or refresh the memory with books or plates? If any of you intend to become army surgeons, or to practise in the country, remote, perchance, from other Medical aid, how can you predict the hour at which you, in like manner, may be summoned to operate for strangulated hernia, to open the trachea, to cut down upon abscesses deeply situated in the neck, axilla, or other important and intricate regions. And yet, not one of these operations can be attempted with safety to the life of the patient, with due regard to the peace of mind and reputation of the surgeon, without a masterly knowledge of anatomy. It is a common enough delusion to imagine that a general knowledge of anatomy suffices for practical purposes. This is a fundamental error, replete with danger to the safety and welfare of mankind. If we aspire to follow Medicine as a science, to benefit others and ourselves, our knowledge of it cannot be too minute or too accurate. You may ask, "How much knowledge of anatomy is absolutely requisite?" The question is difficult to answer. If I must give a precise reply, I would do so in the words of the illustrious Beclard:—"The surgeon should understand anatomy so thoroughly and perfectly, that, when he plunges his scalpel into any region of the body, he should be able to strike the part he seeks, and avoid whatever may be endangered, with as much certainty as though all were transparent, and his gaze fixed upon the point of the knife." Allow me, then, once more to urge upon you the necessity for industry in the prosecution of this, the first division of our labour. Let no sophistry damp your ardour—no pleasures mislead—no fears deter you. Use the means, and the end must come. Even if at first you are unable to perceive your advance, be not discouraged. Set forth with the conviction present to your minds that anatomy and physiology constitute the tree of Medical science, and you will feel that the earlier and deeper its roots strike, the more abundantly will its flowers and fruit bloom forth in season. By an easy step we pass from the contemplation of normal structure and function to consider the several perverted conditions to which these are liable—in other words, to the study of disease or pathology. In the prosecution of this division of our labour, it is wholly unnecessary for me to call upon you for increasing vigour and application. The end and object of your study is to enable yourselves to combat and alleviate disease. To do so you must first learn to understand its nature, causes, effects, and tendencies. How is this knowledge to be obtained? Whosoever of you hopes to win it must begin, as I have already set forth, by the study of anatomy and physiology, wherein alone are found standards with which to compare altered structures and functions, and measure the amount of their aberration from health. Thus prepared, you must industriously investigate and patiently analyse disease itself by the bedside, and in the dead-room. Allow me to impress upon you the truth, that in proportion as you excel in the knowledge of normal structure and function, will you become acute in your discrimination of deviations therefrom; verifying the words of Marshall Hall, who tells us that to become good physicians we must become good physiologists. Of all the special means whereby to acquire a reliable and intimate knowledge of disease, there is none equal to the habit of recording notes of the various cases which come under view. There are many and great advantages peculiar to this much-neglected practice. In the first place, the mere fact of committing to writing the details of cases from their commencement to their termination, implies an amount of attention never bestowed under other circumstances. Of the necessity for this concentration of the mind upon the subjects of study I should scarcely venture to speak, were I not convinced that no error is more common among students than of confounding attendance at hospital with attention to the cases. Let me assure you, gentlemen, that the first without the second is mere waste of time. Again, the natural desire to render the history as faithful a representation as possible of the case in point, educates and refines the power of observation, and gives quickness and accuracy to this, of all faculties, the most indispensable in the investigations of natural science. To comprehend fully its utility, bear in mind that in the several branches of natural science, the mode of advance contrasts directly with that in mathematics. While in the latter we start with a few principles, and argue and construct from these, in the former we must begin by observing ultimate facts, then by reflection reduce them to classes, and thus arrive at general laws. It would be difficult for me to lay sufficient emphasis upon the incalculable importance of cultivating a reasoning and fruitful power of observation in the study of our Profession. The sooner you acquire it, the more profitable your labours will become. Remember that it will avail you little merely to see phenomena of health and disease. You must also learn to perceive their import. It is hardly needful to quote illustrations in corroboration of what I state. The whole history of the advance of Medical science is but a record of the reflective observation of its wisest followers. Nearly six thousand years had rolled by from the creation of man; through ages and ages hundreds had dissected and beheld the structure of the human body; and yet it remained for the acute perception of William Harvey to discover in

the uniform direction of the valves in the nervous system—a starting-point from whence to reason out and demonstrate the circulation of the blood. What an amount of accurate knowledge of disease previously unnoticed, has been contributed within the last half century by the labours of the keenest observers, who have shed the lustre of their genius upon Medicine, such, for example, as the researches of Laennec and Stokes upon affections of the lungs; of Corrigan upon cardiac diseases; of Graves on exophalmic goitre; of Bright on renal degenerations; of Addison on melasma; of Brown-Séquard on nervous affections; and of a countless host of labourers in the same field of usefulness. For all this, and other progress, we are indebted to the simple fact, that these distinguished men perceived and profited by what others saw and passed unheeded for centuries untold. The habit of case-noting possesses many advantages in addition to those already enhanced. It exercises constant personal familiarity with disease, engraves its lineaments indelibly upon the memory, and soon accumulates a mass of valuable experience for reference and assistance in difficulty. The late Mr. Colles was remarkable for his extraordinary knowledge of disease—so much so, that patients often were astonished at the accuracy with which he was able to recount their symptoms. To this he attributed to his habits of case-taking. The late Sir Benjamin Brodie and Trousseau tell us emphatically, that the records of cases noted during their practice, have proved throughout their long and eminently successful lives constant and faithful guides in circumstances of perplexity and doubt. There are a few practical suggestions relative to case-taking, which I think may prove useful and which I will therefore venture to offer for your option. In the first place, in order to simplify matters, always commence by the description of the case, just as it presents itself. Thence proceed to track out the past history, and conclude with details of treatment and progress. Again, make it your rule seldom or never to seek assistance of others in the task. When finished, submit the whole to the correction of your clinical teachers, but during the process depend rather upon yourselves—on your own judgment and observation—and upon the evidence of your own senses—even if at first your trouble be great, and success questionable, persevere in this self-reliant course, confide as little as possible in the prompting of others. Do not for a moment misunderstand me, suppose that I undervalue the information you may gain from your clinical teachers, from your lectures, and from books. Far otherwise. I would only caution you against misjudge its value, or imagine that useful and practical knowledge of science can be obtained by any other means than personal labour. Bear in mind the words of the illustrious Harvey, who expresses himself so happily upon this point:—"If we content ourselves," he says, "with the observations of others, the sprightly edge of our wits will languish, and we extinguish the lamp which they lighted to our hands. It is those who follow Nature's conduct with their own eyes (sometimes through a perverted yet faithful tract), who attain the highest pitch of all." "Let us blush," he adds, "in this so ample and wonderful field of nature, where performance still exceeds what is promised, to credit other men's traditions only. Nature must be our adviser, the path she chalks must be the walk. While we confer with our own eyes, and turn our eyes from meaner things to higher, we shall at length be received into her closet secrets." I have endeavoured to make clearly before you the great advantages which you must infallibly derive from the practice of case-noting, in the cultivation of pathological science. But, you will ask, is there no other description of study advisable? Unquestionably there is. Experience, however valuable as a means, avails itself without system and thought. Beyond the accumulation of a heterogeneous mass of information, there is obviously something needed to satisfy the scientific investigator, and impress a philisophic character upon the whole it—in a word, the deduction of fundamental principles and the construction of general laws, from reflection on numerable ultimate facts. Here we are, doubtless, arrested by serious difficulties, and for a reason sufficiently obvious. The astronomer may push back his generalisations to the very law of gravitation, but in it, though incomprehensible, he finds something unchanging and constant. On the other hand, we seek to force back our explanations to final causes, and there we are encountered by the protean meteor, "vital force," which, wavering with each case, everchanging, casts before us a fresh mystery, which neither physician can unravel, nor chemist analyze, nor philosopher understand. Still, though our embarrassments be disheartening, we must not lose our courage, but labour hard to generalize what we can, remembering that, in proportion as we elucidate principles of comprehensive scope, we enhance the versatility of our resources to confront the various phases of disease. Therapeutics, the last portion of our task, still remains to be considered. Of its importance you will form a just estimate on reflecting that your other studies are but means to this end. You learn anatomy and physiology to prepare yourselves for the study of pathology. The sole utility of comprehending disease is to enable you to treat it upon a rational foundation. How, then, may a sound knowledge of therapeutics be acquired? As anatomy and physiology lead the way to pathology, so the latter prepares for therapeutics. In a word, we must add to a comprehensive knowledge of disease a versatile acquaintance with the power and use of remedies. The brief time at my disposal renders it impossible to enter now, at any length, upon this all-important subject. Therefore, at most I can but roughly sketch an outline of your course, and we must postpone the rest until our clinical conferences give time and opportunity for more complete investigation. Above all things, if you would make your therapeutics scientific and really useful, study their true relation to disease. Master the natural history of all the diseases that come beneath your observation, and learn to see in disease rather a vital condition than an entity. Ponder upon the efforts of Nature to heal, and ascertain the tendencies of various morbid states to cure or death. Thus prepared, reverently, but courageously, wait upon Nature; try to learn her mind, and obey it; be her pupil always—her master never. Humbly take to heart her great lessons, as mere apprentices, indentured to her to assist and imitate her restless task of reparation. Falter not because your office is subservient, but think only of all the good you may accomplish. Medicine and surgery have before them a magnificent future; all things tend to show that, as years pass, it will be their glorious task, more by standing out of Nature's light than by kindling candles of their own to diminish pain and lengthen life. A few hundred years ago, childbirth was three times more fatal than now; small-pox decimated continents; plague, black sickness, and leprosy raged in Europe. How different now! Life is longer in every grade than formerly—small-pox is virtually annihilated as an epidemic—the plague is never heard of—and chloroform, that fairy-gift of chemistry, has robbed the surgeon's knife of all its terror. I would I might pursue this theme, but I must not trespass on your patience, and, therefore, hasten to conclude. It is no portion of my duty, gentlemen, to arraign the faulty system of education—preliminary and special—to which you are subjected. It is not my place to do so, and it could serve no useful purpose. Beyond doubt you have opportunities enough of learning your Profession, provided only you choose to take advantage of them. I conceive, however, that it is incumbent on me to point out, so far as I am able, those erroneous and mischievous impressions against which you should struggle in the prosecution of your studies. Of all the evil influences which overshadow the education of the modern physician, none, I am satisfied, is comparable to the almost universal neglect of extra-professional mental culture. The licensing bodies at large, with a few honourable exceptions, vie with each other in setting at naught the general education of the student. Probably we owe this serious error, in great measure, to the utilitarian character of the age; but, surely, law-givers should stand above such an influence where so much is at stake. I allude to this point in order to impress upon your minds the means of prosecuting, on your own account,

the cultivation of your intellectual powers, outside your special studies, if you desire to attain superiority in the Profession of Medicine. It requires but little reflection to understand the force of what I state—a mere glance exhibits the necessity, indirect and direct, of an enlarged education for success in the pursuits of our Profession. If, indeed, its subject-matter were definite and limited, it might, with some plausibility, be urged that general education was not so indispensably requisite. But, as I have endeavoured to show you, the physician is engaged in a struggle to master a subject, which, from its very nature, is partly beyond his comprehension, and over which his control must be proportionate to the extent of his sagacity and the perfection of his mental training and resource. Moreover, he is in direct need of a most liberal education to fit him for the acquirement of that portion of knowledge which is actually within his command. Without an acquaintance with classics and modern languages, the very phraseology of the Profession is unintelligible, and many of the richest sources of information are cut off. Without the cultivation of the reasoning faculties it is very difficult to attain that logical precision of thought which saves from error, and guides in the search for truth. Without a competent acquaintance with physics, mathematical and experimental, it is not possible to appreciate or profit by the characteristic improvements of modern Medicine. If time permitted, I might here profitably enter upon the consideration of the remarkable effects which applied physics have produced in the science of Medicine within the last fifty years, illustrating my theme by pointing out the services rendered, and likely to be yet rendered, by various scientific aids and appliances, such, for example, as chemistry, the stethoscope, laryngoscope, endoscope, and ophthalmoscope—each one of which, in its proper department, has rendered diagnosis more or less completely matter of demonstration, certain in place of inductive and speculative. I am confident I cannot better enforce the drift of my argument than by quoting for you the following sentences from Dr. Stokes' memorable address on Medical Education:—"Let us, then, labour as we best may, to diminish the lets and hindrances which beset the study of Medicine. Let us labour to place the teaching of Medicine in its true position. Let us emancipate the student, and give him time and opportunity for the cultivation of his mind, so that in his pupilage he shall not be a puppet in the hands of others, but rather a self-relying and reflecting being. Let us ever foster the general education in preference to the special training, not ignoring the latter, but seeing that it be not thrust upon a mind uncultivated or degraded. Let us strive to encourage every means of large and liberal education in the true sense of the term, and so help to place and sustain our noble Profession in the position which it ought to occupy." It may, perhaps, be thought by some here present that the study of Medicine, such as I have dimly shadowed it out, and such as I conscientiously believe it to be, is an undertaking too discouraging to attempt—too hazardous to embark in. Be not disheartened by the magnitude of the task before you, but simply take the lesson to your advantage, by reflecting on the necessity and omnipotence of the work—life-long, well-directed work—which alone can help you to the goal at which you aim. Others have done what you seek to accomplish, and which needs only a stern will and a brave heart. Remember that the famous Dr. Arnold, of Rugby School, has stated that, in his experience, the difference in men was not in ability, but rather in energy. Gentlemen, I have now, to the best of my ability, completed a task which I undertook with reluctance, feeling its importance and my own inadequacy. I have submitted to your consideration those views of the nature and objects of the Profession of Medicine, as well as the proper means for attaining a knowledge thereof, which, in my humble judgment, are most just, and capable of guiding you safely through your arduous undertaking. I feel that it is time to be silent, and only regret my discourse has not been more profitable. Gentlemen, I have no inclination to inflict upon you the customary moral lecture, nor to tell you what conduct becomes you as students of Medicine. Suffice it if I can succeed in making you feel the dignity and charity of your calling, and all that I could add follows, though unspoken. Then, it will be needless to remind you of the kindness, gentleness, and delicacy with which you should treat the poor sufferers in the hospital wards, as those stricken by poverty, affliction, and suffering—as God's chosen ones—as your brethren—and as the living books from which you must learn all that will bring you success and distinction in after life. Remember, once for all, your mission is "the mission of Mercy," even like unto that of the good sisters who surround us in this hospital of the Queen of Mercy. If you cannot emulate their disinterested and exalted motives, at least take pattern from their gentle ways. Imitate their kindly devotion, their untiring patience, their dauntless courage. I hardly like to touch, even in passing, upon the fancied drawbacks which are at times supposed to detract from the worth of our noble calling. If I must only allude to them at all, it shall be briefly, and to disabuse your minds of prejudices which a little time, without my aid, must dissipate. It is a not uncommon practice, with a certain class of the public, and even of the educated, flippantly to depreciate the Profession of Medicine, urging that it is wanting in scientific basis, evil in its tendencies, and of doubtful social position. We, who understand better, can afford to bear such aspersions, in pity rather than in anger; for all who take the trouble to understand it, apart from its practical art, Medicine is a science, and the grandest of sciences. Day after day brings to light new proofs of the truth of its general laws, and of their co-relation and intimate connection with the dogmata of physics in general. Medicine is none the less a science, because being inductive, we have no universal axioms from which to deduce the individual facts of disease; because we are obliged to elucidate its laws synthetically by the comparisons of a host of particular instances, and in many cases are forced to reason by analogy and hypothesis. Neither is it the less a true science, because it is an imperfect one, perplexed and confused by the intermixture of vital with physical phenomena—in a word, by the immediate contact of the spiritual with the material. The variations in the practice we adopt at different times, in all diseases bearing the like names, has in ages excited the ridicule of the weak-minded, and constituted, for the ignorant and superficial, a ground of bitter attack. You will understand most thoroughly the value of such observations when sufficiently advanced in the study of your Profession to appreciate the doctrine I have endeavoured to inculcate—namely, that disease is not so much an entity as a vital condition—that it is not the name of the malady, but the state of the patient, you should seek to treat. Nay, more, when you shall have arrived at comprehending the extraordinary change of type that disease has undergone within the last forty years—that change so exhaustively demonstrated by Alison, Watson, Christison, Graves, Stokes, and others—you will come to perceive that the very alteration of treatment quoted in ridicule of the supposed inconsistency of Medicine, actually constitutes the most overwhelming vindication of the fixity of its principles. If Medicine, dealing with fluctuating vital conditions pursued through all an unvarying line of practice, then, indeed, it might justly be arraigned for inconsistency. I shall not delay to consider the slanders occasionally uttered against our Profession in common with other branches of natural sciences—namely, that its tendency is irreligious—that it disposes to materialism and antagonism with revelation. The imputation is empty and groundless so far as science is concerned, and can only refer to the just judgment which sometimes overtakes that pride of intellect to which St. Paul alludes when speaking of the "knowledge which puffeth up and perisheth." The truths of nature are the truths of nature's God, and surely, we may in all humility expect, and patiently await the hour when a more expanded comprehension of physics shall clear away all seeming contradictions, and annihilate such cavils in the obvious conformity of science with revealed religion. I shall not here dilate upon the social position of the Profession of Medicine. Unfortunately, it is too true that many influences, some difficult, if not impossible, to

remedy—some painful event to think of—have depressed it below the just standard. So far as this consideration is at stake, I think we shall act most wisely by accepting our calling for its own sake ; by struggling, each one according to his ability, to elevate it in the estimation of those around us. For ourselves we need have no misgivings—most assuredly, if our Profession has disadvantages, it also has grand attractions. That which can only be the occasional luxury of others—the relief of pain—the mission of mercy, above all distinctions—is our daily task. That which is the recreation of few, save the rich and leisurely, the wondrous operations of nature, it is our constant business to study and commune with ; we follow no dubious principles of right and wrong ; we are harassed by no scruples of mind on conscience ; we truckle to no caprices, acknowledge no worldly dependency but follow in freedom a life at once useful and bounteous to others—elevating and independent for ourselves. If our Profession offers no great chances of emolument on the other hand, it seldom, I believe I may say never, fails to procure a competency. If honours and public distinctions come to it like angel's visits, the blessings of both rich and poor fall thick as the showers of Heaven. If our toils are great and slavish—if for success we must defy fatigue, exposure, risk, and danger to our very lives—still there are rewards amply sufficient to recompense us. Our vocation is a sacred one, not a means to an end, but the end itself. Neither should we ever waver from its prosecution to follow that glittering apple, which once was thrown before Atalanta, and ever since has let and hindered the course of those who stooped to pick it up. Worldly prosperity is an incident, not an essential, to our calling, but our true honoraire is the memory of insufferable pain relieved, the rescue of valued lives from premature death, the restoration of fathers and mothers to their helpless families, and the saving to the hearth the limbs of little ones that seemed doomed to die. For all this the physician may reap innumerable thanks, inexpressible gratitude ; for his he may earn a name, if not renowned, at least beloved. And when, in the inscrutable ways of Providence, his toils prove vain, his efforts void, even still though baffled the true physician is not wholly at a disadvantage. That man must die is an inevitable truth, and who can know it better than he who so oft looks on, the unwilling witness of the sombre visits of "That shadow cloaked from head to foot, who *holds* the key of all the creeds"—that shadow which, certain as existence, one day or other lays its relentless hand on every child of Adam ; sometimes tearing from life with all the apparent cruelty of an avenging spirit ; sometimes gently wooing by mild decay : or sometimes so stealthily gliding upon the unsuspecting victim, and, as it were purifying dissolution from all its more revolting aspects, that the very soul itself, dazzled by approaching immortality, fails to recognise or understand the emancipation at hand. Bystander at these scenes, and fully conscious of all that is passing before him, the physician holds office of thankless responsibility, for good or evil. He can whisper, when needful—the moment when earthly hopes are waning and when it is time for the poor sufferer to bid farewell to all that is human—and thus he may oft bestow a blessing in comparison with which all passing aid is indeed as nothing. For himself he can take a thousand lessons, each more precious than the other. From aught that is sudden and untimely in the fate of others, he may learn in his own case, the worth of timely wisdom. From the magnificence and gorgeous harmony of the little he can see and understand, he may seek to picture the wonders of those circumstances and phases of being which outstrip his present knowledge, to realise the truth that the beauty of life is overwhelmed by the grandeur of death, which, so far from being the mere defeat of human skill, or end of existence, but in the expressive language of the ancients, but the portal of life undying." And when he stands by the death-bed scene, where sorrowing friends weep and mourn the spirit of one they love, just disenthralled from its earthly tenement, wings its way to the realms of eternity, he may seek, in mind, to follow its path, and elevating his soul beyond the paltry cares and passions of his mortal career, may learn to hope and long for the day when the brightness of infinite truth shall penetrate the mists that encircle and overshadow his intelligence, and merge all doubts, all uncertainties, all speculations, all theories in the fulness of the knowledge of the Almighty Creator and his wondrous works.

STEEVEN'S HOSPITAL—DISTRIBUTION OF PRIZES.

The annual distribution of prizes to the successful students at Steeven's Hospital for the Session of 1864-5 took place in the theatre of the hospital. George Woods Maunsell, Esq., presided.

Mr. E. Hamilton, Honorary Secretary, read the report, after which the Chairman presented the prizes and honours, and then addressed the meeting. He said after the report which had been read, it became his duty to address a few words to those present, and he thought he would best discharge that duty by calling attention shortly to the position of Medical Education, and to touch upon those points with which a layman might appropriately busy himself. There were many reasons connected with the Medical Profession why it should be the pride and the object of every one that this Medical school should be found equal to itself in proudly sustaining the reputation which was gathering round the head of the Profession generally. They believed that the Medical school connected with Steeven's Hospital was second to none in the United Kingdom. (Applause.) They found year after year a growing zeal amongst the students, and the competition which had been evinced this year in contending for those distinctions which are awarded at the close of the session indicated the industry and the capability of the gentlemen whom he saw around and before him. He thought he would not be treating them nor the question with the respect to which it was entitled if he ventured to enter on it without first giving the subject proper consideration. He had, therefore, put on paper such ideas as occurred to him. Mr. Maunsell then referred to the duties and responsibilities of the Medical Profession, than which no profession exercised a greater influence on the social relations of life, and for these reasons it was of the last importance that the members should be properly qualified for the discharge of their important duties. He referred to the measures which had been taken to relieve the Medical Profession from monopolies, leaving it to depend solely upon its merits. He argued that it was plainly the duty of the State to take care that proper qualifications were obtained by those entering the Medical Profession. (Hear, hear.) It was in pursuit of the honourable qualifications for the practice of their Profession that the students were present that day, and to secure these qualifications, general education in the first place, should be extensive and could not be too liberal, to impress this principle on them he could not do better than quote the language of one of the highest ornaments of the Profession in this city, Dr. Corrigan, who, on speaking of this subject, said "that Medical pupils being permitted to commence with a low preparatory education the deficiency could never afterwards be supplied. Medical students often commenced their Professional studies without being able to spell—without knowing the rudiments of Greek or Latin, and incapable of writing out a description of the cases that might come under their notice in hospital. These students were afterwards rejected at the military, naval, and civil service examinations ; their Profession was a failure, and their hopes in life were blasted. They suffered the penalty but the fault was not theirs, but lay with the universities and colleges in admitting these students to commence without previous preliminary examination, and with the legislature in permitting it." That statement, coming from one of the most eminent of the body, was deserving of great weight with those whom it most concerned. To extend their general education should be the great object of every student, and here it was that Dublin presented so many advantages in her public libraries, museums, laboratories, galleries, &c., all of which were storehouses of general instruction, easily accessible to all ; still, their chief business there lay with the technical and more strictly Professional

education, towards which reading and anatomical lectures would do much ; but true knowledge of disease and its mode of treatment was best attained by diligent attendance in the hospital wards, every bed of which had a story that he who ran might read. He referred to the great public services which Steeven's Hospital had rendered humanity in attending to the wants of the sick poor. The endowments of the hospital, as had been stated by Mr. Cheyne Brady, fell far short of its requirements. There were 250 beds in the hospital, but the means at the disposal of the institution would not allow the maintenance of more, on an average, than 180. In reference to the proposed improvement in the building, he said that they were still deficient of several thousand pounds in the sum necessary to carry them out. These were the days, he said, when philanthropy was active, and when, if wealth was piled up, it was, in many noble instances, bountifully distributed, and he hoped they would yet see the day when some one would walk in the steps of the previous benefactors of the hospital—the Steevens, the Cusacks, the Bowens, the Parnells, &c., and afford the means to make that great institution what it was intended to be. (Hear, hear.) They should not forget that, side by side with the princely foundations of London—St. Bartholomew's, Thomas', Christ's Hospital—two merchants of London had raised an hospital that stood equal to any. There aspirations here were more humble, but their career was not less known. They might suffer somewhat by delay, but he had faith in the ultimate success of a good cause fairly stated, and he trusted that most, if not all of them, would live to see funds contributed, the work done, and Steeven's hospital presenting a perfect arrangement from top to bottom, of which its friends and the country might feel justly proud. (Applause.) He trusted the observations he had made might not be deemed presumptuous from one who had devoted some study to the matter. If they should be the means of drawing the attention of his young friends to those important subjects which might hereafter effect their progress in life, he would feel that their time had not been unprofitably employed.

THE LEDWICH SCHOOL OF MEDICINE.

The Inaugural Address at the opening of the Session 1865-66 in this School of Medicine was delivered in the lecture theatre, by T. P. Mason, M.B., F.R.C.S.I.

We subjoin an abstract of Dr. Mason's discourse.

"Medicine, as practised at the present time, may be ranked as one of the highest of the inductive sciences. It has for its object and aim the lessening of human suffering, the alleviation of pain, and the lengthening the span of life. It thus ministers to the holiest aspirations of the human heart, and calls forth the highest efforts of intellect to relieve suffering humanity. Our purpose here is to treat disease, to raise from the bed of sickness to the full powers of life and intellect the stricken in every degree, alike extending our aid to the poor in their wretched abodes as well as to the wealthy in their luxurious dwellings—for the primary object of the true physician is not personal gain; the end and aim of this science is to confer on mankind the highest benefits, not only in curing disease, but also in diminishing the susceptibility to its destructive influences. To achieve those ameliorating results such men as Jenner and Hunter have lived. For those purposes has Medicine been raised to its present lofty position by successive labourers, some of whom have spent the best years of their lives without any adequate reward except the conciousness of having done their duty ; whilst others have freely laid down their lives in their efforts to rescue the sufferer from the grasp of death, as the annals of the plague and typhus fever can testify. Medicine, as practised in the earlier ages, was degraded to the level of a mere mechanical art, or so clothed by mysticism (as practitioners either arrogated to themselves, or were supposed to possess, supernatural powers), that few were disposed either to study the Profession or respect the professors. The impediments which I believe chiefly prevented the progress of our science in ancient times were—first, the defect of elementary information, especially in anatomy and physiology, through the horror which existed as to human dissections, so that men were not only ignorant of the healthy structures and functions, but knew nothing of those organic changes on which symptoms depend. Directly arising from this state of things were false theories. Vain men form imaginary laws in their closets, and attempt to bind Nature to them; theories and their founders pass away, whilst those immutable attributes which the great Creator has indelibly impressed on humanity remain for ever unchanged. To learn those laws by patient investigation becomes our duty. With the cultivation of anatomy Medicine at length emancipated itself from its long night of darkness. Anatomy may thus be said to be the alphabet of Medicine ; it is the guide which enables the surgeon safely to use the knife for the removal of deformity, for the suppression of hæmorrhage, by a bold and timely operation, to save life. Apart from these higher gifts which anatomy confers on the surgeon, a knowledge of it is essentially necessary to the proper understanding of surgical disease. . . . Let me, therefore, impress on the junior student the necessity of a continuous study of practical anatomy, inasmuch as it gives the key to the knowledge of the structure of the complex machine he will be called on by-and-bye to treat. . . . You must work for yourselves individually ; you must unravel each separate region, and dissect out and trace to their several terminations the large arteries and nerves of the body. . . . Your business is to observe the phenomena of life; and there can be no better mode of educating your minds to observe facts, and follow them up by exact reasonings, than by adopting the preliminary method of making yourselves acquainted with the relative positions and normal structure of the different parts of the body. Anatomical study thus apprentices your minds to strict Medical observation. . . Physiology is the science which explains the natural processes and endeavours to account for them. This science may be considered as a modern one. The labours of Haller, Harvey, Bichat, and other illustrious workers in the same field have laid the foundation of a correct science. The vague generalities of Hahl, Hoffman, and Boerhaave have disappeared, and more precise theories of the actions of life have taken their place. Physiological science has received an immense impetus by microscopic investigation and the discoveries of organic chemistry. . . . I would not think so meanly of any of you as to imagine for a single moment that you would be content with an inferior place in your Profession; for I am firmly convinced that the true road to Professional fame and competence is by your possessing within yourself all the attributes which the dignity of your Profession and the public good demand from you as educated Practitioners, equally ready to treat a case of fracture or of typhus fever. To attain this useful and honourable position it is necessary that each of you should work, and should take advantage of the means so amply provided for you to cultivate your minds in order to develop those qualities calculated to render you successful practitioners. The elements which are said to be necessary to eminence in our Profession are a capability of minute observation of facts, an attentive investigation of disease, and an accurate inspection of the dead body. Those are the attributes which are most likely to ensure you success and eminence, and the cultivation of them becomes an imperative duty which you owe to society. Anatomy, physiology, and pathology form thus the ground-work of Medical science; but in order that the knowledge they confer may be made available in the treatment of disease, there is a branch of your studies which never should be neglected—I allude to hospital practice. . . . Your attendance at hospital should be constant, never omitting a morning. Each individual case should be carefully observed and thought over, the results carefully registered in your minds. By properly noting a number of cases, the course, treatment, and termination of which you have personally observed will confer a fund of positive experience on which you can always safely draw in the future difficulties of practice. . . . There is no profession which demands from its members higher or purer principles of honour. Our practice should ever be governed by principles of the highest rectitude,

oth in our intercourse with society and with our Profes-ional brethren. Our minds should ever be under the ;verest discipline, lest at any moment an unguarded obser-ation might escape our lips which would be the means of eating domestic misery, or of breaking that confidence hich had been reposed in us. . . . On the her hand, whilst by every honourable means you en-avour to gain the confidence of your patients as a means more perfectly treating their diseases, never fawn upon, nder, or cringe to them. Never either feed their credu-y, or prey upon their fears as a stepping stone in some ercenary or other dishonourable object. Well may the ofession cry shame on such mean and dishonest acts. nduct such as this lowers us in the estimation of all right and honourable men, and robs us of the fame ich is the common property of all. . . Oppor-nities are constantly arising when we might, by looks or rds. injure the character or Professional fame of a brother ictitioner, when he in reality does not deserve it. In those cases a high principle of honour should guide us. r conduct should be governed by the common but beau-il Christian rule, 'do unto others as you would they ould do unto you.' By thus rendering to every one what his due and exacting from others your due, you will omplish the object of supporting the general stock of ofessional character. . . . The tutorial tem has for its object an intimate union between pupil l teacher whereby the latter is enabled to direct the mer, in his course of reading, to select the most judicious oks for study and point out on all occasions the best de of overcoming the difficulties which the student ets in its progress. It facilitates the student on his lsome path and smooths those difficulties which might pede his onward march. Whilst the teacher does his ty by you it is necessary that you should second his orts, and by earnest application repay, in part, the tious care and early training you have each received m fond parents. By diligence in improving the means thin your reach show your appreciation of the early sons you have received from maternal lips, and deavour to realise those hopes and expectations ich are centred in you—work with constant and un-ing energy for the noble prize which is within your sp and your efforts will be crowned with success, adopt-; as your motto those fine lines of Longfellow :—

'The star of the unconquered will
He rises in my breast,
Serene and resolute and still,
And calm and self-possessed.' "

CHMOND SCHOOL OF SURGERY AND MEDICINE.

he Introductory Lecture in connection with the Rich-nd, Whitworth, and Hardwick Hospital School of licine, North Brunswick street, was delivered in the ture Theatre of the Richmond Hospital by Dr. J. T. ks.

he lecturer commenced by endeavouring to impress on Medical students before him the importance of giving ious consideration to the choice of a profession. He sed them to consider well whether they were prepared ursue a Profession which called for so much research heir part, and was attended with so much labour. y should also consider whether they had adopted Profession hastily, or whether they had any tion for it. They had also to ask themselves whether had received an education of a nature suited to lop their reasoning powers, and such an education as essential to success in the Medical Profession. Educa-for this Profession should be at least equal to that re-ed for the sister professions. An intimate acquaintance classical literature was all important. Education, no er how it was acquired, was valuable, but the lecturer cipally valued an university education. An acquaint-both with ancient and modern languages was most ssary. To become a scholarly physician or surgeon, the practitioner should be able to read with ease continental literature, and especially those standard Medical works, so many of which were written in the French and German languages. The lecturer, having dwelt at considerable length on the subject of education, condemned those licencing bodies which too readily granted licenses to practise Medicine and Surgery to the half-educated and unskilled persons, but said that he was happy to state there were some honourable exceptions. The Dublin University and the University of Oxford were pre-eminently distinguished for the high standard of education which they required from those who sought to become members of the Medical Profession. He considered that Cambridge did not study the credit of the Profession when it resolved to grant licences to those whose education did not exceed "the little go," or half the course. The learned lecturer then spoke of the value of the study of chemistry and anatomy, and said that the cure of disease was only to be learned in the wards of the hospitals. Nor could those intended to become surgeons neglect the Medicine wards. Medicine and surgery were inseparable, and the study of Medical diseases was one which those who were intended for the army or navy could not neglect. It appeared that out of 200,000 of the French army who entered French hospitals, 150,000 suffered from Medical diseases, and only 50,000 from wounds. Dr. Banks then directed attention to the study of Irish typhus, and the diseases of the mind. After referring to the prospects which Medical men had under the Poor-law Board and in the army and navy; the learned lecturer expressed his great satisfaction at being able to state that the Medical officers of the army had, in proportion to their numbers, compared with "combatant" officers, obtained more rewards for personal valour. Not only did they well perform their duties in the hospital, but on the field of battle they showed so much courage that many of them obtained the Victoria Cross.

THE CATHOLIC UNIVERSITY SCHOOL OF MEDICINE.

The Inaugural Address for the winter session 1865-6 of the Catholic University School of Medicine was delivered in the Lecture Theatre, Cecilia street, by Dr. Haydn, one of the physicians of the faculty. The chair was taken by the Roman Catholic Archbishop of Dublin.

Dr. Haydn came forward and delivered the following address :—I feel on the present occasion the difficulties incidental to addressing a mixed audience. I see before me on the one hand several gentlemen not of our Profession, who have honoured us with their presence, and expect to hear something interesting, if not instructive to them ; and, on the other hand, those distinguished and respected seniors of Medicine, whose presence here to-day is a testimony that this school at whose inception ten years ago many of them assisted, has not disappointed their expectations, or failed to win by earnest labour and honourable means, a position of equality with the many excellent institutions of a similar kind in our city ; in the same category, because also enlightened in Medicine, are the senior students who have nearly completed their period of study, or rather of their pupilage, because study is equally an inheritance of all practitioners and pupils alike. To these, or such of them as have fulfilled the obligation they owe to themselves and to society, I would address a word of congratulation on time well spent, and the immediate prospect of emerging from the stage of embryo Professional existence into active Professional life, and of encouragement to persevere in a course which will ensure them a clear conscience and an honourable competency, if not always an independence. But to those senior students who have misspent their time, who have wasted their means, and learned nothing save habits of indolence and dissipation, I would say, even now at the eleventh hour try and repair, by redoubled energy, the losses you have inflicted on yourselves, of time, of money, of moral character, and self-respect, and what, to a Professional man, is a

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause thereof, and have made such arrangements as will prevent the possibility of a repetition of the same. Any gentleman not having received his copy as usual during the last three weeks, will be kind enough to intimate the same to the Publisher.*

WEDNESDAY, NOVEMBER 8, 1865.

THE MEDICAL CIRCULAR.

POOR-LAW MEDICAL REFORM.

The Poor-law Medical Reform question may now, we think, be truly said to be approaching a new and improved phase of its existence. Hitherto the abuses connected with the management of the sick poor have been discussed almost entirely in the pages of the Medical Journals, and even in most of these, it must be confessed that the exposures of the existing system have been few and far between, and that the cause of the Medical officers has been but feebly advocated. Such, in fact, was the petty tyranny exercised by the Boards of Guardians towards their Medical officers, such was the supineness of the Poor-law Board, and such was the disunion among the Profession itself, that any fair and honest discussion on the grievances complained of was almost impossible. Any Medical officer who candidly set forth his own annoyances, and demanded investigation at the hands of some competent tribunal was shelved as soon as possible, and all inquiry as to his complaints was refused by official inertness. Rather than endure the continued insolence of the local Boards, many of the most efficient Poor-law Medical officers threw up their appointments, but their places were immediately supplied, and the object of the Guardians was equally accomplished—namely, to get rid of honest men who advocated the interests of the sick poor. Those who maintained their position against the Guardians were refused a hearing by the Poor-law Board, and those who resigned in disgust contemptuously left their successors to fight the battles in which they themselves declined to engage. Thus, from a variety of causes, the prospects of Poor-law Medical Reform have until lately been very gloomy; the Medical Profession has suffered in silence, and the Guardians, under the protection of the Poor-law Board, have had everything their own way. The horrible dens in which the sick poor have been huddled together, the gloomy Bastiles in which many of our suffering fellow-creatures are perennially immured, have been carefully concealed from public inspection, while the disgraceful mode in which the sick were accommodated and nursed was known only to the Medical Officers, who, as we have just remarked, had the best reasons possible for keeping the knowledge to themselves.

But a new and unexpected light has been thrown upon these dreary abodes, and upon the treatment of their inmates, by some casual and accidental circumstances which have recently transpired. One or two Coroner's Inquests upon cases of death occurring in workhouses found their way into the general newspapers; and although the cases themselves were far from being of an extraordinary character, being, in fact, of no intrinsic importance whatever, yet they served, during a season of dearth in political excitement, to stimulate the curiosity of the public, and to open its eyes towards abuses which had long existed, and against which the Medical Officers had over and over again remonstrated in vain. It was then discovered, as if for the first time, that the pauper, instead of being a creature of inferior importance to a dog, or a horse, or a pig, was a human mortal like ourselves, and that the suffering he endured in illness, and the treatment he experienced at the hands of the Guardians, might become our own lot if we should perchance fall into poverty, destitution, and disease.

Great was the exultation of the 'Times' at this notable discovery, and all the smaller luminaries of the Press echoed the sentiments of their leading organ, and as might be expected, a great share of the blame of the existing arrangements was actually laid at the door of the Medical Officers! and one of the newspapers seriously suggested that the surgeon of the workhouse, in one of the cases to which we allude, should be indicted for manslaughter! These pretended guides of public opinion knew perfectly well that the fatalities brought to light were only the necessary results of a vicious system, and yet they endeavoured to shift off the responsibility from those who perpetuated and defended the abuses, on to the shoulders of those who were themselves the slaves and the victims of Poor-law mismanagement. But this attempt to lay the burden of guilt upon the unfortunate workhouse surgeons recoiled upon itself, and the further discovery was eventually made that the Medical Officers, like the miserable sick paupers, were actually objects of public sympathy rather than of blame and vituperation. Then our contemporary the 'Lancet,' inflamed by sudden zeal, published *in extenso* the results of some visits to metropolitan workhouses, and although the facts it communicated were quite well known, or might have been known, by anyone who took the trouble to inquire, yet the revelations as to the diet, ventilation, nursing, and other accommodation or want of accommodation afforded to the sick paupers, came upon the public with the air of novelty; the sensibilities of the multitude were shocked at the details, and people asked, not unnaturally, what the Poor-law Board were doing to allow such enormities to exist?

Now, the attitude of the Poor-law Board may be easily explained, although the explanation is by no means creditable to that body. The Board at Whitehall has an absolute control over the whole of the working of the Poor-law system, and although some of the workhouses are not actually included in the unions, they are all subjected alike to the central authority. The Inspectors of the Board have a legal right (which they exercise whenever they please), to visit and report upon all the workhouses, and we assert that all the abuses which have been recently

rought to light were perfectly well known to the Board, nd yet they took hardly any steps to rectify them. The uthorities of the Board defend themselves on the plea of eir unwillingness to interfere with the local Guardians, rgetting that they are constituted for the express purpose f standing between the weak and the strong, and of en-ring to the pauper his legitimate rights as a member of e commonwealth. Sheltered by this miserable plea of pediency, the Poor-law Board has winked at, if it has t positively encouraged, the misdeeds of the Guardians; s suffered the continuance of those miserable dungeons which the sick poor are confined; has sanctioned the gradation of the Poor-law Medical Officers, and has con-ibuted to the neglect of the sick and the helpless.

Now, however, because the newspapers have taken p the matter, the Poor-law Board rubs its eyes, and akes a pretence of zeal on behalf of the poor; and we nd, instead of the former policy of truckling to the uardians, that the Inspectors of the Board are threat-ning the local authorities, in case of disobedience to s mandates, to put in force the provisions of an Act which ey are expressly appointed to administer! This out-irst, however, is like the awakening of Rip van Winkle ter his twenty years' sleep, and causes the greater tonishment from the lethargic slumber by which it was receded.

But whatever the cause may be, the present aspect of fairs is favourable to Poor-law Medical Reform, and we rdially recommend our brethren to rally round Mr. riffin, who has proved himself a true friend of the Pro-ssion.

SUMMARY OF THE WEEK.

THE NATIONAL TEMPERANCE LEAGUE.

On Friday evening last, the Lord Mayor of London vited a number of gentlemen, many of whom were of e Medical Profession, to partake of tea and coffee at the nsion House, and afterwards to meet a deputation from ociety called "The National Temperance League," and to ar an exposition of the objects of that body. Accor-ngly a pretty large meeting, including seventy-one of e leading physicians and surgeons of the metropolis, embled on the occasion; and after an economical distri-tion of refreshments, the guests were entertained with eries of speeches, embodying most of the exaggerations, s-statements, and false conclusions which are usually lulged in on similar occasions. It is only right to men-n, however, that the leaders of the total abstinence move-nt appear to be actuated by a sincere and honest desire improve the morals of the community by discouraging, far as they can, the immoderate use of fermented liquors, d it must be admitted that in recommending and practising eir system they are doing themselves no harm, and e probably effecting some amount of good. But when ey leave their legitimate sphere of operations, and begin attack the Medical Profession as being the advocates of e use of strong drinks, and when they accuse us of couraging drunkenness by recommending the thera-peutical employment of alcoholic fluids in certain cases of disease, it is quite time for some one like Dr. Webster, who spoke on Friday last, to point out the fallacy of their arguments, and the mischief which may follow from the adoption of their doctrines in the extreme degree in which they are propounded. For ourselves, we regard alcohol as a blessing or a curse, according to the manner in which it is employed; and as much may be said of many other moral and physical agents or weapons which may be handled by mankind. There is no doubt that drunkenness is one of the great evils of the age, and it has been an evil ever since the origin of man as a rational being, and in nearly all countries of the globe; but no person in his senses can deny that the drinking habits which prevailed in England in even recent times are very much reformed, owing to the improved manners of the present day. Again, although it is quite true that the use of alcoholic drinks does often lead to disease, and all Medical men would readily indorse such a statement, yet it is also true that multitudes of the destitute and even hard-working poor of England become ill from the want of food and a moderate amount of stimulants, and that the same want prevents them from getting well when they are ill. Take a thousand people of the lower classes who are made ill by alcoholic drinks, and Medical men (especially those who see much of dispensary and hospital and pauper practice) can probably point out a thousand others, especially women and children, who are starving or half-starving on weak tea and bread and butter, and for whom a glass of good beer and a modicum of meat would be the best medicine to be administered. It is quite true that the beer may be replaced by bread, meat, milk, or soup; but on economical grounds we are induced to think that a pennyworth of sound porter is about as good an investment of a penny as a working man or woman can make in the way of food.

THE HIGH PRICE OF MEAT.

Among the advantages possessed by those who live under free institutions, there is one disadvantage—namely, that the price of articles of food is never regulated or interfered with by the Government. If such interference were permissible at the present moment, it would probably be found that while the community in general are suffering most grievously from the high price of meat, there are persons behind the scenes who are really reaping large gains from the scarcity, or pretended scarcity, which the nation is called upon to deplore. The existence of disease at present among cattle is undeniable; but if we are correctly informed, the prime cost of meat in the market is the same now as it has been for some months or years; the supplies from abroad are abundant, and some people, we suspect, have reason to pray for a continuance of the cattle-plague, instead of its disappearance.

CYCLOPS' TWENTY-SIXTH LETTER ON PHYSIOLOGY.

To Vigilans.

Sir,—Proceeding from my last letter, let us consider the physiology of "The Lion and the Cow." The former is an animal full of muscular strength, on which his very existence depends. He is ever watchful and vigilant, for his powers may be called upon at any moment for attack or defence. He is exposed to the air night and day, in his natural state, and is incessantly on the alert like all this class of animals who have to provide for themselves. He is no doubt often greatly pressed for food, yet does not seek it till he feels the pangs of hunger, and then he has often to wait some time before he can get it. Now we naturally ask how he gets his powers of endurance and his strength,

for often from the climate, which is his habitat, the lack of water forms one great feature. What could prevent these animals from fevers and sometimes total annihilation, considering the immense amount of oxygen which they must consume. When in the extremest hunger, they have seized their prey, they suck its blood and devour the more juicy parts, then, having gorged to their full extent, they slink away to their lairs in the deepest recesses, simply because they should not be disturbed. A child with a club might approach and kill them at such a moment; but empty and hungry, and full of muscular and fierce strength, a giant (without a rifle) is no match for them. Here, then, we see a carnivorous animal, living in a tropical climate, often pressed for food and water, yet strong, and all his muscles well lubricated with fluid. Besides which, he is able to make an immense amount of the salivary juices, of bile and other secretions, to be used again in the system, and which are absolutely necessary for the digestion of his immense meals, which we see he gets only when he actually wants them, and these at longer or shorter intervals. We are then told that he does not have an evacuation of his bowels oftener than once a month, and then he deposits the smallest portions of mere earthy matter, scarcely worthy even to be called fæces. Can the arterial blood supply him with more than structure? Can the venous blood supply him with more than diluents for his new ingesta, and for the necessary and immense proportion of bile such a creature requires? Where are all the other lubricating fluids to come from, as well as the vital secretions necessary for such a brute, living in such a manner? Here, then, we see Nature's bountiful provision in supplying hydrogen to the very utmost extent from his fæces, because otherwise we cannot account for the immense quantity of fæces he must make from such meals as his, compared with the small amount he actually gets rid of. Now, one of two things must occur, if the hydrogen was not generated, and when generated have oxygen to combine with it in sufficient quantities, and thus furnish to this animal very many pints of fluid in every twenty-four hours. The hydrogen would either poison him, or the oxygen would wear out all his tissues, and from his natural caloric and carbon he would be subject to fever, and so be burnt up. Can any other physiological law explain why his colon is so conservative an organ, or how all these vital powers are maintained in their integrity, except in the way I have now propounded.

Let me put the case of a gentleman in juxtaposition with the lion; one who lived for more than twenty years in the driest and most arid part of Mexico. In that time he saw Europeans out of number consigned to their parent earth. Fevers, dysenteries, diarrhœas in all their forms, carried them off, while he never had an illness. He was one of those men who were satisfied to be in health under his peculiar idiosyncrasy of insuperable constipation. He never suffered from thirst as others did; he never had a fever the whole time he was there. His constitution is even now entirely unaffected from his long residence in such a place, and he had sense enough to guard him from the pest of Medical empiricism, cathartics. But every two or three weeks he had his little scybalous action of the bowels. He thus preserved the moisture in his system, provided by Nature by the union of the hydrogens he generated himself and the oxygen of the air, in which he lived, independent of what he drank; while he saw that the Europeans, who insisted on having their bowels relieved, sink around him, and those that had any tendency to looseness, unless they could get away in time, would soon die, and there was not the slightest hope for anyone who had dysentery. Yet these things are happening everywhere, and physiologists take no notice of them.

Now, let us take the cow. What is she? A large mass of indolent aggregation of fluids; she lives only to make them. Her powers are totally opposite to those of the lion. She has not to provide her food by her own exertions; she is a helpless, stupid animal, only fitted for what she is, to graze from morning till night in the fattest pasturages; to be loose in all her muscular fibre; to carry a large proportion of fat and bulk; to have intestines highly distended; to drink largely; to increase her species at every available period, and from the constant action of large milk glands, to yield their fluid to the greatest extent. This milk is no secretion from her blood. Is there a physiologist adventurous enough to say that the milk is a product of the blood? It is enough that her arterial currents supply structure, for her venous currents are far greater in proportion to them. From what she must consume, we must infer that her own secretions are immense. Her colon is large, and though she may have a semi-fluid motion every hour, still it is always full. We must therefore infer that hydrogen in its purest form, unmixed with much sulphur or phosphorus, is the gas alone which is eliminated from her excrements. Living as she does, or ought to do for health, almost always in the atmosphere, the oxygen she consumes is necessarily large. The union of these gases supply her flabby tissues with many pints of fluid in every twenty-four hours. Kept in this moistened state, she is what we see her, and could only be this quiet, docile animal, yielding quarts of milk daily. If cows are kept as they are in London in sheds, and never from the time they go into them to the time they are past the uses which man can make of them, to be fed and milked, fed and milked, night and morning for years, our only wonder is they remain in health at all. Nothing but their inert natures, the undisturbed serenity of their peculiar characters, with just sufficient oxygen to combine with the hydrogen they themselves make, with only the commonest care though often unwisely kept in half-cleaned stalls. Yet still they live and furnish, though not so largely, their fair proportion of milk. The healthy balance of their secretions is due only to those unerring laws of Nature, the union of their gases, but being free to a great extent from those which the carnivora and omnivora generate in the colon, they are less susceptible to disease from morbid conditions of their secretions generally. The thin, lean cow soon fails in all her duties and usefulness to man. Her poor appearance being due to the two causes, of not making hydrogen sufficient for the oxygen she consumes, and therefore with less power to resist the atmosphere in which she lives. Can any one, viewing these two animals in their separate and distinct natures and modes of living, come to any other conclusion but that conservatism of the fæces in the one, and a constant semi-fluid condition of them in the other are the result of natural laws, and that to reduce either to the condition of the other, would do violence to both. We see the one, the king of the forest, wiry and above all, carrying no flesh or fat. His whole frame, well and firmly knit together, muscles, more like a mass of tendinous fibres, lithe and lissom and ponderously elastic, with a brain power endowed with instincts on which his life depends; the other, all the reverse, with scarcely an instinct for her own preservation. The life and powers of the one dependent more on the conservatism and value of his fæces than on his food; that of the other, in respect to her usefulness to man on her succulent food, but on the constant discharge of her fæces, because excess of other gases than hydrogen should never occur, and so reduce her value and the general purity of her body.

From all these facts we can deduce a law of idiosyncrasy in those individuals who have their regular daily motions, and those who have conservative habits. The various epochs which this conservatism takes vary from every other day to two months. Since I first investigated this subject some twenty years ago, I have known many hundreds of individuals and very many entire families who had no regular actions of their bowels, but with habits varying from a week to a fortnight or three weeks. Where observation has once been put on the track, information of these apparently remarkable conditions of the system accompanied by the highest state of health, have been brought to me. An intelligent chemist in the country told me a countryman came to him for something to act on his wife's bowels, for she had been put to bed with a child six weeks ago and had had no motion since. He was so alarmed that he told the man he had better go to his doctor. "That's no use, he knows all about it," said the man, "his wife always went six weeks." Again, a friend of mine had the following fact from the best

uthority: An old gentleman in the country who was nety-seven years of age, had never, since he was sixty, ore than six motions a year, one every two months, nd would always joke with the doctors, and say they ould have killed him years ago if they had had eir way. I have heard of a colonel in the army ho did not have a motion sometimes for six months, nd then nothing to signify. Probably like the lion, some ry earthy matter. Let then, physiologists be once put on the right scent in all these matters, and they will me to the conclusion I have arrived at for many years—amely, that the value of the fæces as fæces in the body as been overlooked; that the very anatomy of the colon, s I have shown in previous letters, clearly indicates that ature has resigned it to be conservative at important eriods of everyone's existence. That if we take all the ost valuable secretions of the body which are made by it be used again, such as the saliva, gastric juice, the muco-embranous secretions, the bile and a thousand others—k e, I say, all these from every source and combine them, ey are not then half so valuable as the fæces. These pply all the organisms with those gases which Nature equires to resist the atmospheric elements and pressure in hich they are destined to live. It is not only the resisting owers which are offered by these, but the fluid elements hich are generated from their combination with their posites, and that all our brain power, as men, are due to em; so that though the fæces are not used as other elements of the body, they yield from their whole mass throughout the whole length of tube, they have to pass through ul from the constant opposition offered to their passage, st amounts of gases of the most important and necessary aracter, and vital to the whole bodily and mental structure. As all these are matters of health, regulated according to the idiosyncrasy of every individual, I shall conclude is, and in my next will show the beneficial action of conservatism of the fæces in disease. I am, &c.,

CYCLOPS.

The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

OPENING OF THE DUBLIN SCHOOLS OF MEDICINE.

(Continued from page 331.)

rcely less misfortune, the vitiation of the habits of gularity and application to duty. To the junior students, wever, I would principally direct my observations, as y stand most in need of advice and guidance. I would them to bear in mind what Medicine is, the spirit in ich they should embark in its cultivation; the means which success in the study and practice of Medicine is be attained, and the discourageme its inseparable from s, as from all other human pursuits. Medicine does not sist in the discovery and administration of "specifics," which there are and can be but few, because there are paratively few diseases of the nature of morbid poisons. ore Medicine was properly understood, and even still mgst the unenlightened, the idea prevailed that disease in all cases a separate entity, possessing a distinct ividuality and objective existence. Advancing knowge, however, shows that the number of diseases that it this distinction is comparatively small; and within own time several to which this dignity had been rded have been reduced to the commonplace level of rdered nutrition, deranged function, or their consence, the production of hybrid tissue or compounds. have a good illustration of this in rheumatism, a ase not long since supposed to be objective in its aracter, but now well understood to consist in a group of ngements, the consequence of retention or accumulation he blood of one of the transitional products of the version of starchy substances. The immediate cause of retention has not been made out, but, doubtless it mately will be; and then it may be said that our wledge of rheumatism has attained to the level of being scientific. Long, however, before this knowledge shall have been arrived at, the "art" of Medicine, as distinct from the science, may minister effectively to the relief of rheumatics. In this consists empiricism, which in so far as it represents the supplementing of defective knowledge by experience and sagacity, is entitled to the respect and attention of Medical practitioners—not only because it contributes something, however little, to the relief of suffering and the cure of disease, but because it may afford a clue to the ultimate discovery of the precise nature of the affection, and the proper mode of treating it. Many other examples might be given to illustrate the doctrine that disease is essentially derangement of function, arising from or resulting in impairment and deterioration of the organs and fluids of the body. From this the inference is plain, that the first step in the study of Medicine, without which no progress can be made, consists in the acquisition of an intimate knowledge of the structure and functions in the state of health, of the several organs and tissues of the body; of the composition and purpose of its various fluids, nutrient, digestive, and excretory. In other words, anatomy and physiology in the broadest sense, including not only general or descriptive, but likewise structural or microscopic anatomy, and the growth, chemical constitution, and disintegration of the solid and fluid elements of the body, from the essential basis of Medicine as a science. In the disease known as leukhmia, the white blood—corpuscles (exhibits diagram), are in excess; this change in the constitution of the blood it were impossible to discover without the aid of the microscope, and even when observed, the change could not be identified, or its significancy appreciated, without a previous knowledge of the relative numerical proportions in which the red and white corpuscles normally exist in the blood, and of the important purposes which the former subserve in the economy as the passive agents in the oxydation of the tissues, the stimulation to functional activity of the nerve-centres and muscles, and of the conduction and distribution of animal heat. Fatty degeneration of muscular organs affords another example of disease, sometimes of a most formidable character, of which Medicine would have remained ignorant were it not for the aid of the microscope. As regards general anatomy, it seems unnecessary to point out the importance of forming an early acquaintance with its various details. The ardour with which this department of Medical study is cultivated in the several Medical schools of Dublin, shows that students are fully sensible of its importance, and renders any arguments to enforce it quite superfluous. Not so, however, microscopic anatomy, which, I regret to say, is not as much cultivated by the students of the Dublin school as the few examples above given suffice to show it deserves to be. In the London and other schools, a microscope is held to be a necessary appendage of the students' dissecting apparatus. In this school, from its foundation, microscopic anatomy has been perseveringly taught; and, besides two class prizes, a University gold medal and an exhibition of 20*l.* have been founded with the view to encourage the cultivation of it, in conjunction with physiology and chemistry. Medicine, then, being a rational science, based upon demonstrable truths and admitted postulates to an extent quite sufficient to entitle it to that designation, it behoves those who would acquire a knowledge of it, such as this practical age and enlightened period of the world's history will alone admit to be competent, to enter upon the study of it with earnestness of purpose, and with minds free from bias in favour of any of the exclusive and exploded theories of a former period, or the Medical heresies of modern times, and to pursue it in a methodical manner, and with close and intelligent application, as in other departments of human knowledge. But Medicine is also a progressive science, and in this lies at once its difficulty and its charm. We are constantly reminded of certain forms of disease which Medicine is unable to cope with, and not unfrequently even to explain. These have been reproachfully termed the *opprobria medicinæ;* but to those who indulge in such ungenerous reflections the answer may be given—Medicine is a composite and progressive science; the phenomena with which it has to deal

are partly physical and partly vital. The former, by far the more numerous, lie within the domain of physical investigation, and have been in great part examined and made a portion of certain knowledge. In the elucidation of these most of the physical sciences have been engaged, and where failure has resulted, it is to be attributed to the imperfection of those sciences, and not to any backwardness in the votaries of Medicine itself as a distinct subject of inquiry. For example, the precise agency by which an interchange is effected in the lungs between the carbonic acid suspended in the venous blood and the oxygen of the inspired air, has not been even yet fully made out, notwithstanding that physicists as well as physicians have been engaged in the inquiry from the time of Lavoisier and Laplace to the present. Similarly, the apparently simply and purely physical phenomenon of the first sound of the heart, though repeatedly investigated by some of the ablest philosophers of the last two centuries, from Harvey to Lænnec, and from Lænnec to Skoda, is still one upon the precise causation of which the widest divergencies of opinion exist. In regard to the action and changes due to the principle of life or purelyvital phenomena,the difficulty of interpretation is still greater, because here science can aid us only to the extent of registering the operation of an unknown agent; but even here much has been, and yet more may be, done—for example, the precise nature of nerve force, though in many particulars resembling electricity, still remains, and probably always will remain, a mystery. Helmholtz has, nevertheless, measured its transmission in the fog, which he has found to be at the rate of eighty to ninety feet in the second; and in man, making allowance for the difference in his nervous organisation, he concludes the nerve current travels at the rate of about 160 feet per second. If there be, then, so much difficulty in the interpretation of physical and vital phenomena in the normal state, or under the operation of physical and vital laws, how formidable must not that difficulty be in regard to the same phenomena under the disturbing and ever varying influence of disease? As regards morbid action, in the extensive and fatal class of zymotic affections, although the actual discovery of the nature and qualities of the morbific agent has not been achieved, owing, no doubt, to its subtlety, still, considerable progress has been made in that direction, as evinced by our recently acquired knowledge of its genesis, diffusibility, and the mode of its prevention. Of a similar tendency is the evidence afforded by the remarkable discovery made by Sigri and Pasteur, of the existence in organic fluids undergoing fermentation or decomposition of innumerable minute infusorial animalcules, termed backteria; and the subsequent discovery by Devaine of baccerides in the blood of sheep suffering from carbuncular disease or splenic apoplexy, and the communication of this disease to healthy animals by innoculating them with fresh blood taken from those infected. I have selected these examples to show that Medicine is not stationary—that it is steadily advancing, notwithstanding the great difficulties that oppose its progress, difficulties mainly due to the complex nature of the inquiry, and the extensive and practical acquaintance with physical science, which those must possess who would be its pioneers. But all, or even the greater number, cannot take a foremost place; there is, however, work for all to do—the work of the good Samaritan and the good physician. Those who have not a heart to feel as well as a hand to execute, and the knowledge to guide it, are not fit to practice the noble and humane profession of Medicine. I cannot envy the man who would treat his suffering brethren as so much inanimate matter, forgetting that the patient and practitioner are alike endued with sensibility, and that gentleness of manner and sympathy contribute in no slight degree to alleviate pain and promote the action of remedial agents. You will, then, labour in the first place to acquire a knowledge of your Profession, prosecuting your studies systematically and assiduously under the guidance of your teachers, commencing with anatomy and chemistry, which make you acquainted with the form, relative position, and general structure of the various parts of the body, and the properties and laws of combination of matter. Having acquired this elementary knowledge, you should next proceed to the development and application of it in the higher departments of structural or minute anatomy, physiology, and practical chemistry. At the same time, that is, in the first year, you should study botany, or the classification, structure, and functions of plants, as an introduction to the study of their properties, and therapeutic agency, which will be taught you by the Professor of Materia Medica. And now, having acquainted yourselves with anatomy, physiology, chemistry, botany, materia medica, and forensic medicine, or the mode of inquiring into or reporting upon the cause of death, you will be prepared to enter with profit upon the study of surgery, practice of medicine and obstetrics, in which is taught the application of the knowledge previously acquired. You should diligently attend hospital from the commencement of your studies, if only to become acquainted with the physiognomy of disease; but even whilst junior students you will learn much more than this, which is in itself of great value—you will be taught the method, and will acquire the habit, of investigating and distinguishing disease in its various forms; you will observe the signs of improvement or retrogression under different modes of treatment, and as your knowledge increases so likewise will your practical acquaintance with the objects upon which it is to be subsequently exercised. If possessing an average ability, you pursue the course here pointed out, systematically and perseveringly, you need have no fear of the final ordeal of examination. I would warn you against the evil of neglecting your studies in the early period of your course, in the erroneous conviction that you can "pull up" further on. This is a fatal mistake, because the basis for a scientific knowledge of your Profession, if not laid in the first years of your studentship, is never laid at all, and subsequently, under the pressure of approaching examination, and entirely possessed by its terrors, you will acquire only a wordy knowledge which, "like the baseless fabric of a vision, leaves not a rack behind." The incentives to the study of Medicine are chiefly the attractions inherent in the subject itself, which affords so wide a field for observation and discovery, and in which each important addition to knowledge made by us may be the means not only of alleviating pain and prolonging human life, but likewise of bringing wealth and distinction to ourselves. In the words of Mr. Paget—"The wages of student's work are not paid in his student's life, but they are most surely paid in after life; for the more knowledge he gains the more able he will be for practice, and the more able he is in practice the better will be his reward; so that on every ground, whether of duty or of interest, the only rule I can lay down is, get all the knowledge you can." But there is a reward even higher than this, which those can best estimate who have been the victims of remorse for duties ill-performed, or confidence misplaced—it is that of a satisfied conscience, and the happiness even here below derived from the hope of a future and better recompense. Young practitioners should be prepared for a certain amount of discouragement and disappointment. Professional success does not follow, as a logical consequence, from Professional merit; tact, punctuality, upright and honourable conduct, and gentlemanly demeanour, are important accessories to Professional knowledge, and the want of them will neutralise the highest Professional attainments. I would urge you, therefore, from the outset to make these by habit, as it were, a part of your nature. Mr. Paget, in the admirable lecture from which I have already quoted, says truly—"If a man will be always impracticable, always uncourteous and ungenerous in his estimate of others, always self-willed and self-complacent, it is no wonder if he does not succeed in his Profession, or if he requires for success more, much more, knowledge than is necessary for a better temporal rival—if a man will be always unpunctual, inconsiderate of the inconvenience of others, indifferent to the welfare and comfort of his patients, and indifferent to his engagements, it is no wonder if his Professional ability is not compensated by a proportionate amount of success. There is

othing unfair in all this ; it is not a property of our Pro-ssion alone, for the same mental defects spoil the good sults of knowledge in every other calling." By a recent gulation of the Medical Council, the first step has been ken towards raising the standard of education amongst edical students. This is as it should be, for most suredly the interests of the Profession, and of each mem-r of it, are alike promoted by requiring that every person lding a diploma shall be an educated gentleman. enceforward no person can commence the study of edicine till he has given satisfactory evidence before a urt of examiners that he has received a liberal education. e is then "registered" as qualified to study Medicine, and the end of four years from that date, having gone through e necessary course of education, he is admitted to amination for license to practise. The Medical Coun- recommends, and the recommendation has been gene-lly adopted by the colleges and other licensing bodies, at after October, 1869, no candidate shall be ad-itted to final examination who has not been pre-ously registered; but as registration marks the com-encement of Professional education, and the latter ust extend over four years, it is clear that a period ual to this must intervene between registration and final amination. It has, furthermore, been ruled that no stu-nt can be registered later than fifteen days after the com-encement of the session. Hence students commencing eir studies should bear in mind—Firstly, that they must ss a preliminary examination before they can register, d secondly, that in order to have credit for this year's dy, they must enter their names for lectures, and regis-on or before the 17th of November. It is to be regretted at just grounds of complaint exist on the part of the icers of the army and navy Medical services. No doubt ese services have undergone considerable improvement, d present many inducements and advantages ; still there ems no justification for the exceptional manner in which ese gentlemen had been treated in regard to rank, promo-n, and allowances, and, above all, by the cancelling of e warrants of 1858 and 1859, which placed them in a sition of equality with combatant officers. It has never en pretended that the Medical officers of the army and vy have failed as a body in their duties. On the con-ary, it has been repeatedly admitted that they have been variably distinguished by devotion to duty and fearless llantry, under the most trying circumstances. It is to hoped that when their grievances are better understood, they are soon likely to be, from such able and temperate blications as the pamphlet of Mr. Brown, of Rochester, ich I hold in my hand, they will be promptly redressed the force of public opinion, and that a body of gentle-n of whom the country ought to be proud, and of whom rly fifty have been educated in this school, will be ated with the consideration to which their education, ir Profession, and their eminent public services entitle m. There is another question which has recently en-ed public attention, and upon which a person occupying place I now do may be expected to make some definite nouncement for the information of students, and because settlement of it must, in some degree, affect the interests his school as an integral portion of the Catholic Univer-of Ireland. On this subject, and representing not only Medical department of our University, I will merely erve that we seek for no monopoly, and, as has been truly erved on a late occasion by a high authority, this school s not stand in need of it. We ask only for equality, we should be content with nothing less. Our desire is uphold and to advance education, and the means which e been, and still are found useful elsewhere in affecting t object—namely, the right of supervising, at least a tion of the education of their graduates—we think it not easonable to require that we, too, should be allowed to rcise. We have reason to believe that this just demand not be resisted, and that when we next meet our friends his place we shall be in a position to report the success-operation of the first instalment of justice and equality he matter of education conceded by a liberal and en-tened government to the claims of a much injured and long-suffering people. And why should it be otherwise? The intellect of Ireland is a mine to those who will work it, and the cultivated intellect of catholics, who constitute the vast majority of our people, is no less valuable to the State than of their fellow countrymen of any other form of religious belief. Let there be, then, equality, political and educational, and harmony, peace, and progress, will be the result.

SAVORY AND MOORE'S FOOD.

The principles on which Baron Liebig suggested a New Infant's Food were first made known in England by a paper in 'Hardwicke's Popular Science Review,' but the preparation of the food involved considerable time and trouble, until Messrs. Savory and Moore made it available for general use by presenting it in a form in which the different materials are so blended together, that the addition of water and boiling milk is all that is required to make it suitable for consumption. The articles prepared by Messrs. Savory and Moore are Liebig's Extract of Beef and his Food for Infants. The former was intended by Baron Liebig to be added to and consumed with vegetable food, as it is deficient in albumen, fibrin, fat, and gelatine, although it contains several other animal principles and salts. The Food for Infants consists of the same ingredients and in the same proportions as those recommended by Baron Liebig, including even potash, and the only difference consists in the malt-flour being more finely ground, the wheat-flour lightly baked, and the temperature in cooking being carefully observed; the boiling and straining being consequently avoided, as recommended by Dr. Hassall. In the original formula given for Liebig's Food, both these operations were enjoined ; but it occurred to Dr. Hassall that they might both be omitted without any detriment to the food, and the boiling was proved to be unnecessary by reference to the fact, that at a temperature of about 150° Fahr. the starch-granules, when in water or milk, swell up, burst, and are in fact cooked.

OBITUARY.

JOHN LINDLEY, Ph.D., F.R.S.

We regret to announce the death of Dr. Lindley, whose name has for many years past been intimately associated with the progress of botanical science. Although not a Medical man, he contributed largely, though indirectly, to the progress of Medical science by his great attainments as a teacher of botany, and as a writer on that subject. He was born at Catton, near Norwich, in 1799, and was the son of a nursery gardener. After leaving the Grammar School of Norwich, he devoted his attention to practical botany; but in 1819 he published a translation of 'Richard's Analyse du Fruit,' and in 1820 a work entitled 'Monographia Rosarum,' in which he described several new kinds of roses. About the same period he contributed to the "Transactions of the Linnæan Society" various papers on botanical subjects. Some time afterwards he proceeded to London, where he became Assistant-Secretary to the Horticultural Society, and was engaged by Mr. Loudon to write the descriptive portion of his 'Encyclopædia of Plants,' the merit of which, as a botanical work, was entirely due to him, as was stated in the Preface. The 'Encyclopædia' was completed in 1829. In the same year he was appointed Professor of Botany at the then London University, and was the first Professor of Botany in that institution. At that period the Linnæan system was almost universally followed by English botanists, and it is one of the chief merits of Dr. Lindley that he early saw the necessity of superseding the artificial by the natural classification of plants. In an essay on this subject, published in his 'Introduction to the Natural System of Botany,' published in 1830, he showed what the advantages of this system were, and thus paved the way for its general adoption in England. Two years later he published his 'Introduction to Systematic and Physiological Botany,' and a 'Synopsis of the British Flora,' in which

latter our indigenous plants were arranged and described for the first time according to the natural system. In his 'Natural System of Botany,' published in 1836, Dr. Lindley took new views of botanical classification, and proposed a new nomenclature for the families of plants. Ten years later, his great work 'The Vegetable Kingdom,' was published. This work, the most elaborate that had appeared on systematic botany, gave a description of all the families of plants. It gave very extended lists of the genera and was generally recognised as one of the most important contributions which had at that time appeared on the classification of the vegetable world. While engaged in writing these works, Dr. Lindley was most diligently employed, as a practical botanist, in describing new species, on which he wrote a large number of papers contributed to botanical publications. For more than a quarter of a century, Dr. Lindley filled the chair of botany at University College, London (the former London University), and in 1860 was appointed examiner in the present University of London. He was a Doctor of Philosophy of the University of Munich, Fellow of the Royal, Linnæan, and Geological Societies, and corresponding member of many continental and American learned bodies. In 1858, he received the medal of the Royal Society in reward of his services to modern science. Dr. Lindley had edited the horticultural department of the 'Gardener's Chronicle' from its commencement in January, 1841, to the present time—within two months of twenty-five years.

[Dr. Lindley was one of the most successful teachers of botany in the present day, and through the medium of the numerous classes who attended his lectures at University College, London, and elsewhere, he diffused a knowledge of that science over a great portion of the globe. His style of lecturing was entirely free from ornament, but was concise and luminous, and no person could listen to his instructions without thoroughly comprehending the subject of his discourses. He was utterly destitute of imagination or fancy, and had little eloquence, but he went straight to the mark, and simplified his matter in such a masterly way, as to lead from the most commonplace part of his subject to its most profound philosophy. He was in great measure a self-taught man, and the laborious industry with which he acquired his own knowledge made him the more capable of appreciating the difficulties which might be encountered by others, and at the same time enabled him the better to smooth the student's path. His extensive knowledge of botany, in all its ramifications and applications, may be estimated by his published works, which, as it has justly been observed, form almost a library in themselves, and they testify to the enormous labour involved in their composition. One of the great merits of his earlier works was that they familiarized the public mind with some of the continental researches on physiological and systematic botany, although, to say the truth, he was far from being profoundly acquainted himself with continental languages. An instance of this occurs in one of his books, where in alluding to the researches of Schwann and Schleiden on cell-development, he translates the words *wie ein Uhrglas auf einer Uhr* (like a watch-glass on a watch) "like an hour-glass!" He was a vehement opponent of the Linnæan or artificial system of botany, and took infinite pains to promote the progress of the natural system; but he was unjust to the memory of Linnæus, who was one of the most illustrious cultivators of natural history whom the world has ever produced, and who expressly declared that his artificial system of botany was only a temporary expedient, to be laid aside when a natural system could be substituted, of which he himself actually laid the foundation. The enormous difficulties of establishing a natural system of botany on definite principles may be estimated by the facts that none has yet been universally received, and that Dr. Lindley's own excellent and learned classification is very far from being perfect. The imperfection, however, is not the fault of the author, but is inherent in the very nature of the subject. Dr. Lindley also endeavoured to show that there existed a uniform correspondence between the external forms of plants and their properties and uses, but in this attempt he was only partially successful. In order to illustrate the Medical uses of plants, he published a book called the *Flora Medica*, in which the above views were enforced, so far as relates to drugs, but his knowledge of Medicine was too scanty to make this book of any practical value. As we have before remarked, Dr. Lindley's industry was immense, and it had the effect, eventually, of exhausting his energies. A few years since, his powers began to fail, he lost his memory, which had been very retentive, and he was obliged to relinquish his Professorship and most of his other appointments, and the mischief which had been lurking in his brain finally resulted in an attack of apoplexy, of which he died.]

THE LAST ILLNESS OF THE LATE LORD PALMERSTON.

The 'Lancet' publishes the following.—After a severe attack of gout last year, Lord Palmerston continued gradually to decline in strength, without any distinct complaint till April, when, after riding a rough horse, he suffered from hæmaturia. It was followed by catarrh of the bladder, with its ordinary accompanying symptoms, which occasioned great distress; and this, added to his official duties, reduced his strength considerably, though his remarkably good digestive organs remained unimpared. For the first three months he was attended by the late Dr. Ferguson, in conjunction occasionally with Mr. Paget, who ascertained that there was neither calculus nor any other mechanical cause for the symptoms. After the death of Dr. Ferguson, Dr. Watson was consulted, and, at the end of July, Dr. Protheroe Smith. The treatment they adopted consisted chiefly of tonics and astringents with generous diet and rest, under which Lord Palmerston slowly improved. This improvement was more marked after the conclusion of the session of Parliament, when he retired to Brocket Hall under the immediate care of Dr. Protheroe Smith and Dr. Drage of Hatfield, Lord Palmerston's family Medical attendant. From this time to the 9th. ult. there was a gradual amendment in Lord Palmerston's condition. The purulent character of the urine nearly disappeared; the pulse fell from 100 and 120 to 72 and 76, its customary frequency; and the tongue, from being usually covered with thick brown fur, became clean. On Monday, the 9th ult., the weather having suddenly changed, with a considerable fall of the temperature, Lord Palmerston, during a drive in an open carriage, took cold. Active inflammatory symptoms, with a great increase of pus in the urine, were observed on the following day by Dr. Drage, notwithstanding every effort to relieve which Dr. Protheroe Smith found, on his return from a distant Professional journey on the following Thursday, a great change in the state of his patient. He complained of abdominal and dorsal pains; the pulse was 120, irregular and intermittent; the tongue furred; and there was thirst, and loss of appetite. The urine was less in quantity and of somewhat higher colour, with a remarkable decrease in the amount of pus. In the course of that day severe rigors occurred, followed by symptoms of collapse—namely, cold extremities, colliquative perspirations, and imperceptible radial pulse. From this condition he rallied in about four hours, when Mr. Paget, for whom Dr. Smith had telegraphed, arrived, and, together with Dr. Drage, remained the night, leaving their patient much relieved next morning. Rigors and threatened collapse recurred, however, on Friday and Saturday, on the evening of which Dr. Burrows was summoned from London, and he remained at Brocket Hall that night. On Sunday morning, Lord Palmerston's symptoms were less urgent, and from this time he appeared to rally, though the pulse continued at about 100, the tongue was still furred and dry, and there was abdominal uneasiness. When Dr. Watson arrived at Brocket from Cornwall, on Monday morning, he found the Premier better. Up to Tuesday afternoon he continued to improve, the pulse falling to 80, and the tongue becoming moist; but at that moment symptoms of great prostration again set in, the pulse being thready, and a mucous râle marking each respiration; the gradual extinction of the radial pulse proceeding in inverse ratio with the frequency of the breathing

hich became shorter, and at last reached 54 in the minute. The intellect remained unimpaired to the last. Death took place without a struggle at a quarter to eleven A.M., resulting from catarrh of the bladder and abscess of the kidney.

MEDICAL SOCIETIES.

WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, OCTOBER 20.

MR. G. POLLOCK, PRESIDENT, in the Chair.

Mr. TURNER exhibited a

PHOTOGRAPH OF THE FACE OF A WOMAN

which, in two or three weeks' time, became covered with a thick crop of short and white downy hair. The body and extremities became also covered. The face had the appearance of being painted. She is forty-two years of age, and is suffering from carcinoma of the breast.

Dr. MORELL MACKENZIE brought forward two cases of what he termed

SPURIOUS DIPHTHERIA.

The case was that of a man aged thirty-one, whose uvula, pharynx, tonsils, epiglottis, ventricular bands, and vocal cords were covered with a thick, white, opaque membrane. On the artificial or natural separation (by coughing) of the false membrane, the surface was seen to be inflamed and marked by bloody lines and points. The patient had complete pneumonia and a croupy cough. The false membrane has been present in the throat at least four months. The patient declared that he had never had syphilis, nor were there any evidences of the previous existence of that disease. He had not been confined to his bed for a day since his throat was bad. He felt slightly weak, but the principal inconvenience was the loss of voice. There was albumen in the urine. Dr. Andrew Clark had made a microscopic examination of some shreds of the membrane and declared it to be "crupous lymph." Dr. Mackenzie held that the case presented all the local and pathological features of diphtheria, and that the absence of severe constitutional symptoms alone differentiated it from true diphtheria. Indeed, had the disease occurred in a child, it is probable that the presence of a false membrane in the larynx would have given rise to constitutional fever. In the second case, a lad, aged seventeen, has both tonsils, uvula, and posterior wall of the pharynx covered by a membrane looking like wash-leather, and at least one-sixth of an inch in thickness. He had never had syphilis. His throat had been "bad" eight months, and had been under observation one month. Dr. Mackenzie said that, in the first case, caustics aggravated the disease, and led to the rapid reproduction of the false membrane. The membrane ceased since the discontinuance of local treatment) was slowly declining away. Cod-liver oil and quinine were being given internally. Such cases as these, he considered, went far towards proving that diphtheria, croup, and apthæ were but varieties of the same disease, agreeing in their pathological features, but differing in severity, and modified by the age and constitutional peculiarity of the patient, the surface affected, and by the presence or absence of epidemic influence.

PARISIAN MEDICAL NEWS.

PIGMENTAL SYPHILITIC ERUPTION.

The *pigmental* form of eruption to which M. Hardy directed attention so far back as the year 1855, is important as a characteristic indication of the presence of syphilis in the system, and of the probable period to which infection is referrible. M. Hardy therefore deemed it expedient to point out to his class a young woman recently admitted into his wards, who bore round her neck a sort of ring formed of alternate white and greyish patches surrounded with a dark margin, about half an inch in diameter, not scaly, giving rise to no itching whatever, and so intermixed that at first sight it might appear doubtful whether the white or the grey patches were the diseased parts. The affection consists of both kinds of stain, which, like all ephelides, are the result of improper distribution of the pigmental secretion. The eruption is distinct from *pityriasis versicolor*, in which the circular patches are slightly raised, and occasion evident desquamation and much itching Confusion would more easily arise with *ephelidæ*, to which order, indeed, the special eruption belongs. The diagnosis, however, can be established on the fact that ephelidæ are usually dispersed over a wider space, and are not collected in one spot. The same remark applies to vitiligo, which is characterised by the presence of small, white stains, not intermingled with each other. The pigmental syphilitic eruption most frequently appears in the neck, but may likewise occur on the forehead, the nates, or the abdominal and axillary regions Its progress is also peculiar and the disease often lasts many months, and even as long as two years, defying all treatment, even anti-syphilitic remedies, and finally disappears spontaneously.

The cause of the eruption must be sought for in syphilis, and in syphilis only, and this circumstances has induced authors to designate the affection by the term *Collier de Vênus*, and by the scientific name of *pigmental*, or *maculated* syphilis. It is seldom observed before two months have elasped since contamination, and it is never met with after an interval of two years; it usually appears in the third or fourth month after infection.

M. Bazin contends that the eruption should not be classed with syphilis, because it does not yield to mercurial treatment. It must nevertheless be conceded that mercury is not invariably successful in removing secondary symptoms, and M. Hardy further observes that he has never met with this morbid state of the pigmental structures but in cases of syphilis of three or four months' standing. He opines, however, that a peculiar condition of the skin is necessary for its manifestation, besides the special taint of syphilis. Thus, in twenty instances of the disease, it will occur nineteen times in women, and once only in the male, on account of the finer texture of the integument in the former. The men who are affected are individuals whose skin is unusually fair and delicate. M. Hardy considers the eruption as an undoubted sign of syphilis, and as affording unquestionable evidence of the presence of the taint; in this respect, minute examination of the person of those who present the peculiar discoloration never fails to confirm the surmise its has given rise to.

In the case which suggested the present remarks, M. Hardy, enlightened by the condition of the neck, examined the throat, skin, and organs of generation, and detected the presence of mucous papulæ on the nymphæ, of specific patches in the palms of the hands, probably consequent on a previous papular eruption in the same region, and also a characteristic sore-throat; the patient acknowledged she had recently been affected with roseola, and all the symptoms pointed to syphilitic infection of five or six months' date, although the enlargement of the lymphatics had already disappeared.

In the case of another woman, occupying bed No. 3, supposed to be suffering from psoriasis, M. Hardy accidentally noticed on the neck the peculiar stains of the pigmental eruption, whence he concluded that the psoriasis was of syphilitic nature, and at once prescribed mercurials, which promptly cured the psoriasis, but failed in removing the ephelidæ of the neck.

The Professor related another instance illustrative of the diagnostic value of this kind of pityriasis. One evening, at a ball, he noticed on the neck of a lady, belonging to the best society, the peculiar eruption alluded to, imperfectly concealed by a handsome pearl necklace. He was entirely unacquainted with her, but a few days after, his advice was requested by a person suffering from a pustular and squamose syphilitic affection, in whom he recognised the lady who had attracted his notice at the ball.

It is, therefore, impossible to deny the connection

between syphilis and the pigmental affection we have described.

Beyond this, the eruption is destitute of importance. It should be viewed merely as a reliable indication of the presence of the specific taint, and as a guide to the treatment. With regard to the latter, one local remedy may be resorted to with confidence, and consists in lotions with the following solution, which is also efficacious in other varieties of ephelidæ :—

℞ Hydrarg. bichloridi, ʒj. ;
Aquæ destill., ʒviij ;
Alcohol rectif., ʒiv. ;
Plumbi diacetatis, ʒij.

One tablespoonful of this fluid, added to four ounces of warm water, should be used as a lotion. Shower baths, with sulphurous or alkalised water, may also at the same time be prescribed with benefit.

TREATMENT OF BOILS.

Boils are an inconvenient complication observed in almost every description of acute and severe cutaneous disease, and coincide with herpes zoster, strophulus, eczema, &c. One boil promptly succeeds another, and the affection may thus last a considerable time. We observed in M. Hardy's wards a patient in whom frictions performed on the arm with a camphorated liniment for the cure of rheumatic pains, gave rise to an acute attack of eczema, which induced the development of a large number of boils. Poultices, baths, and aperients were prescribed for the cure of the eczema, but the furuncular eruption persisted, and daily became more and more troublesome, without much perceptible improvement of the eczema. Senna tea, and infusion of wild pansies were exhibited, and subsequently, four glasses daily of tar-water to be taken at meals, mixed with wine. In the course of a few days the eczema yielded, and no further disposition was evinced to the development of fresh boils. Similar results were obtained in other analogous cases, and afforded satisfactory evidence of the efficacy of tar for the prevention of furuncular disease.

In this affection, M. Hardy has tested the value of a host of remedial agents, and is now satisfied that baths and poultices, far from being serviceable, promote the formation of boils. Aperients are all but powerless ; arsenic would probably prove more beneficial, but the very name of the drug alarms the patient, whereas tar-water is a perfectly innocuous medicine ; as it is, in addition, the most effective remedy, it should at once be resorted to.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of the gentlemen who passed their Examinations in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, October 26, 1865 :—Charles Kelly, Market Deeping ; John Coyte Bailey, Plymouth ; George Redford, Normanton, Yorks ; Charles William Huet, Southgate, N.; Disney Thorp, Maldon, Essex ; Griffith Williams Roberts, St. Asaph ; Williams Harris Butler, Old Charlton, Kent ; Robert Fullarton Scott, Calcutta ; John Babington Williams, Monkton, Kent ; Frederick John Burge, jun., Hammersmith. The following gentlemen, also on the same day, passed their First Examination :—John Waller Melson, Queen's College, Birmingham ; Fredk. Boultbee Lardner, Guy's Hospital.

UNIVERSITY OF EDINBURGH.—The following is a list of candidates who received the degree of Doctor of Medicine, the degree of Bachelor of Medicine, and the degree of Master of Surgery in the above University on August 1st, 1865 :—*Doctor of Medicine.*—James Keith Anderson, Scotland ; * George Robinson Barnes, England ; Joseph J. Alfred Besnard, Mauritius ; * Thomas Blunt, England ; Peter Johannes Albertus Van Breda, Cape of Good Hope ; Richard Hake Bush, India ; Duncan Campbell, Scotland ; Antonio Lorenzo, Chiappini, Cape of Good Hope ; William Chisholm, Scotland ; * John Chiene, Scotland ; Horatio D. Steel Compigné, England ; John Charles Compson, England ; John Cook, London ; James Corns, Scotland ; Smith H. Davson, British Guiana ; Thomas John Denton, England ; * Andrew James Duncan, India ; Thomas Evans, Wales ; Philip Sheldon Fentem, England ; Walter Forbes, Scotland ; John Milner Fothergill, England ; David Gentle, Scotland ; Douglas Glendinning, Scotland ; William Henry Gregory, England ; Edward Hoggan, India ; Robert Inman, England ; William Johnston, M.A., Aberdeen, Scotland ; John George Kennedy, Scotland ; Alex. Angus Halley Knight, Scotland ; William Henry Lightbody, Wales ; William M'Donald, Scotland ; * John Aymers M'Dougall, Scotland ; Robert Mackelvie, Scotland ; Roderick M'Laren, Scotland ; * Peter Macpherson, Scotland ; John Morison, Scotland ; George Renton, England ; Sylvester Richmond, England ; Joseph Hildreth Rockett, England ; James Thompson Sabben, England ; Ryk Tulbagh le Sueur, Cape of Good Hope ; Robert Thin, Scotland ; Robert Thorburn, England ; Augustus Werry, Smyrna ; David Wright, Scotland ; * John Wyllie, Scotland.—*Bachelor of Medicine.*—Edward Liveing Fenn, England ; Thomas Prince Fothergill, England ; Charles Bailey Greenfield, England ; Walter T. Prideaux Wolston, England.—*Bachelor of Medicine and Master of Surgery.*—* Lauchlan Aitken, Scotland ; William Armistead, England ; John Barclay Clark, Scotland ; Thomas Hamilton, Scotland ; * William Allan Jamieson, Scotland ; * Robert Kirk, Scotland ; William Hutton Kirkpatrick, Scotland ; Samuel Mitchell, England ; * John Murray Moore, England ; Nath. Daniel Isaac Oman, Scotland ; David Ridpath, Scotland ; James Cunningham Russel, Scotland ; James Spens Torrop, Scotland ; William Pleace Warburton, Prince Edward Island ; George Wight, Scotland ; Julius John Wood, Scotland ; Walter Wilson Young, Scotland. Those gentlemen to whose names an asterisk is prefixed passed the examinations with Honours.

THE Credit Foncier has subscribed 20,000 francs for the sufferers from the cholera in Paris.

DR. B. NORTH ARNOLD, who has just been admitted to the Vicarage of Caverswall, Staffordshire, is a Fellow of the Royal College of Physicians, and Fellow of the Royal College of Surgeons, of London, and practised medicine for many years, taking holy orders in 1862. He served for some time the curacy of Binfield, Berkshire.

ACADEMY OF SCIENCES.—It has recently been stated that the liquor, *absinthe*, owes its intoxicating power merely to the alcohol with which it is fabricated. The assertion is correct, but it is nevertheless true that, in the same dose and at equal strength, *absinthe*, is more inebriating than brandy. This fact, which does not appear to depend on the composition of the fluid, has been explained by its mode of consumption, and M. Péchollier interprets it as follows :—Absinthe, used as a stimulant of the appetite, is usually taken before meals, when the stomach is empty. This circumstance promotes its absorption into the system, and it seems natural to admit that a quantity of alcohol, rapidly and almost entirely admitted into the circulation, must be productive of far more powerful effects than the same quantity taken gradually, and eliminated in part before the remainder has been consumed. It is a fact universally acknowledged, that a certain amount of wine taken in the morning, fasting, has effects far more intoxicating than the same amount drank during a meal. This view is further confirmed by the extremely prompt cessation of the effects of absinthe. All the alcohol swallowed acts simultaneously on the system in a powerful but transient manner. Such is, according to M. Péchollier, the reason of the apparently peculiar mode of action of absinthe.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN, 53 BERNERS STREET, W.—An ordinary general meeting of this Society was held on October 25 last, when were elected B. G. Babington, M.D., and Charles Hawkins, Esq., Vice-Presidents of the Society, also John Scott, Esq., of Harley street, a Director, to fill up vacancies in the list of officers. The Treasurer's accounts for the first six months of the year were also read, from which it appeared that eighty persons, widows and orphans of deceased members of the Society, had received relief, ordinary and extraordinary, to the amount of 1,177*l.* 10s. during that period.

SIR P. DUN'S HOSPITAL.—Surgical as well as Medical cases are to be in future admitted into Sir Patrick Dun's

ital; formerly it received only Medical cases. The quence of this is, that its clinical certificates will now ne of as much value as those of other clinical hos-

E SANITARY STATE OF WEYMOUTH.—The great bene- o society which result from well-conducted house-to- sanitary visits, is clearly shown in the following The local Board of Health of Weymouth lately ed Messrs. Griffin, Tizard, and Samson, to make a -to-house visitation in their respective Poor-law dis- In his report, amongst other valuable information, Griffin says: "I have made a house-to-house visita- f all the houses in Weymouth parish, to the number , and have to report that there are 242 houses with privies, most of which are more or less in a foul In fifty houses, there are open privies connected he street drains. In forty-four houses, the inhabi- se a pail, tub, box, or pan, and empty them by night he harbour, street-gratings, or anywhere they can niently do so without being caught by the police. In stance, a pole serves for a seat. In 101 houses, there place of convenience whatever. Without a regular n of drainage, water-closet accommodation can never ried out. In ten houses, there are cesspools. In 294 , the drains run direct either into the street, under , or harbour. The best remedy for this is an effectual drainage."

ICOSE ULCERS.—Several instances of varicose ulcer recently been observed in the wards, M. Hardy casion to show how promptly these sores heal under mbined influence of rest and of an ointment, of cinnabar and minium are the principal ingredients. atient should be debarred from exercise, and the dressed morning and evening with the following e:—℞ Adipis, ℥j.; Plumbi oxidi rubri, Hydrargyri natis, ā ℥ss. Pulverise on a slab with a muller. A as been effected by this treatment in a fortnight, in f many months' standing.—'Journal of Practical ne and Surgery.'

NEW EDITION OF THE PHARMACOPŒIA.—A "Dis- " writes as follows in the 'Pharmaceutical Journal': President of the Pharmaceutical Conference, in his ddress at Birmingham, states that,—"Judging from tle that is now heard of the subject (the British copœia), one can but arrive at the conclusion, either regulations laid down are widely ignored, or that s, wholesale or retail, are gradually falling in with I hope it is the latter." I would I could hope the I think there has been a great amount of hyper- upon it, from which cause many Medical men ver studied it, at least many daily betray their ce of it by writing P. L. on every prescription, it would be affected by it or not. Oftentimes pre- ns are marked P.L., when officinal formulæ for some ingredients are only to be found in P.B., such as *Quiniæ Citras*, *Acidum Nitro-hydrochloricum dilutum* s not officinal in any British Pharmacopœia previous), and *Extractum Colocynthidis compositum*, which in the last P.L. Dr. Garrod's table "of the altera- strength of preparations of sufficient importance to hem *essential* to be borne in mind in the prescrib- ntains only twenty-four articles; no great bugbear would think. Besides this, it must often lead to isappointment in their practice, as frequently pre- is containing *Tinctura Aconiti* or *Tinctura Nucis-* are not marked either P.L. or P.B., although, from r of the prescription, it may be seen that P.L. is ; yet, in such cases, where they are for internal ration, by erring on the side of caution, the weaker reparation is almost invariably used.

CATTLE PLAGUE COMMISSION.—A report will, we nd, be presented from this Commission this week. ater portion of it is now in print. Without antici- ny part of this official document, we may state one nterest, that under the auspices of the Commission, giousness of the cattle plague and its communica- om oxen to sheep, and *vice versâ*, have been satis- shown. It has been proved by evidence of a positive nature that sheep may be infected, both by exposure to the infection of, and by inoculation from, diseased cows; and a healthy calf inoculated from the sheep has died of the plague. These facts will justify the continuance of a rigid preventive system, however desirable it may be, in the presence of the widespread havoc of the disease, and the numerous foci which now exist, to moderate the despotism of the poleaxe.—'Lancet.'

PAUPER LUNATICS AND BOARDS OF GUARDIANS.—On Friday, Mr. Farnall, the Poor-Law Board Commissioner, opened an inquiry at the Shoreditch workhouse, Kingsland, in a very peculiar and important question relative to the responsibility of guardians for the care of pauper lunatics. The inquiry arose as to whether Shoreditch or the City of London should have the care of a lunatic named Mull, who became chargeable to Shoreditch in July last, and was discharged as cured on the 22nd of August last. About twenty days after he was discharged, he was found in the streets of the city breaking windows, and on being taken before the justices he was discovered to be a lunatic. He was handed over to the City of London Union, the officials of which maintained that he was chargeable to the Shoreditch guardians, who, on the other hand, held that the man was a "wandering lunatic," and was chargeable to the city. James Painter, the master of Shoreditch workhouse, stated that the man Mull was admitted there on the 17th of July last on a certificate given by one of the Medical officers, Mr. Collier, who stated in the certificate that the man was suffering from "unsound mind," which was of a "temporary or permanent character," and might be safely removed to the workhouse. The man was placed in the receiving ward on entering the workhouse, and was afterwards entered in the imbecile ward. He stayed there until the 22nd of August, when he was discharged on his own request on the doctor's certificate that he was cured. Dr. Clark, the Medical officer of the Shoreditch workhouse, stated that he saw the man Mull on his admittance, and treated him while he was in the workhouse. The man had delusions that people were following him to "make game of him," and was, in witness's opinion, quite harmless. His disease was entered in the books as "chronic mania," and witness discharged him, considering the man cured. The Commissioner questioned this witness as to whether he did not think the man would have had a much better chance of recovery in an asylum than in a workhouse, and the reply given was that this case had as good a chance of recovery in the workhouse as it would have had in an asylum. In witness's opinion, the imbecile wards were airy and roomy enough; but he considered the airing yard was small. On reference to the master, it was found that there were about sixty-three male imbecile cases in the house, and only 5,975 superficial feet of airing ground for them. Mary Mull, the wife of the man, deposed that she was sent for by the master of Shoreditch workhouse to take her husband out, and, on her asking what she should do with him, the master told her to keep him quiet and let him have his own way in everything. Her husband was then sent for to her, and told to go out with her, but he had no sooner got outside the wall than he said he would have satisfaction against them, as they were hunting him. He stopped at home quietly for a fortnight, and then took to wandering about frequently at all hours of the night. She went again to Shoreditch workhouse, and the relieving officer said they would admit her husband again if mad, but Dr. Collier refused, on seeing him, to certify that he was mad, and a day or two afterwards he was taken up as described. Other evidence was given, and the case was adjourned for the attendance of Dr. Collier.

LIFE ASSURANCE.—The Briton (and New Equitable) Life Association has just incorporated into its business that of the Britannia, an office of some standing and with a large income.

THE number of cholera cases in the Paris hospitals has considerably diminished. No cholera patient has entered the military hospital of Val de Grâce for the last four days. The deaths are diminishing in Paris at least by ten each day, and two-thirds of those attacked are recovering.—'Gazette des Hôpitaux.'

THE UNIVERSITY OF EDINBURGH.—We understand that there is a good average attendance of students this year in the classes of the University. Last week, Mr. Gladstone, the Chancellor of the Exchequer, made a valedictory address as Lord Rector, the term of his appointment having expired, and he assisted at the reception of Prince Alfred's bust, which is to be placed in the library. Dr. Laycock is to open the Clinic of the University this year, and the managers of the Infirmary have attached a ward to the chair of the Practice of Medicine, in order to facilitate practical instruction. It is said that the withdrawal of Dr. Warburton Begbie has considerably weakened the school of private teachers in the city of Edinburgh.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, NOV. 8.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, NOV. 9.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, NOV. 10.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, NOV. 11.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

MONDAY, NOV. 13.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, NOV. 14.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

To SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause thereof, and have made such arrangements as will prevent the possibility of a repetition of the same. Any gentleman not having received his copy as usual during the last three weeks, will be kind enough to intimate the same to the Publisher.*

MR. B. W.—A review of the book in question has already appeared in our columns.

ALPHA.—The number of Medical students is rather larger this year than the last.

DR. S. H.—The newspaper was received.

SENIOR.—It is true that the eminent Surgeon alluded to treated syphilitic sores without mercury, and without making any distinction between the hard and the soft chancre. The unity of the syphilitic virus is maintained by the advocates of syphilisation.

BOTANICUS.—The Upas tree, the Bread-Fruit, the Common Nettle, the Indian Hemp, and the Hop, all belong to the natural order of *Urticaceæ*. The chief structural peculiarity in this rather extensive order is in the anatomy of the ovule.

X. Y.—The subject is noticed in one of our leading articles.

A LEGAL QUESTION.

To the Editor of the Medical Circular.

SIR,—Can any of your readers inform me which is the proper course to be adopted in the following case? When a Practitioner has been engaged to attend a lady in her approaching confinement, and afterwards the husband of the lady changes his mind and employs another, who attends her—is the first Practitioner entitled to the fee?

I am, &c.,

AN OLD SUBSCRIBER.

[Yes; and within our own knowledge it has been decided in the courts of law.—ED. MED. CIRCULAR.]

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

Brass and Zinc Door-Plates.—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges. Chemists' Shops fitted up with Window-sill Plates in the plain or O.G. Patterns. Lists of Prices post free.
Plates altered and repaired.—Country orders punctually attended to.
36 CHANDOS STREET, CHARING CROSS, W.C.

Treloar's Kamptulicon,
COCOA-NUT MATTING,
AND OTHER DURABLE FLOOR COVERINGS,
67 LUDGATE HILL, LONDON,
Three doors from the Railway Bridge.

William Hawke, Wild Court, Great
WILD ST., DRURY LANE, LONDON W.C., (late Ansell and Hawke), Manufacturer of every description of Shop Fittings, Dealer in Medical Glass, Earthenware, and all kinds of Shop Utensils, Medical Labelling, Writing, and Embossing on Glass.
Drawings, Specifications, and Estimates furnished for Fitting-up Druggists' Shops and Surgeries with every requisite, and for erecting Shop-fronts. Druggists' Stocks and Fixtures valued.

Medical Fixtures and Glass Manufactory,
FACTORY, 3 Liverpool street, Bishopsgate, London
FILMER KIDSTON begs to inform Gentlemen Commencing or Improving in the above Profession, that he has an extensive assortment of SHOP and SURGERY FITTINGS, GLASS, EARTHENWARE, etc., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Stoneware, etc. etc

H. Silverlock's Medical Label Warehouse, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctor's Commons, London, E.C.
DISPENSING LABELS, for the use of Surgeons.
YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, etc.
SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.
LABEL CASES for the use of Surgeons, 14s., 18s., and 24s.
LATIN SLIP LABELS for Wholesale Druggists.
Catalogues sent on application.

Geo. Smith and Co.'s Pure Extract of CALVES' FEET for INVALIDS and CULINARY USE, sold in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Druggists, Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland street, Regent street Office: 94 Upper Thames street, E.C.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.
THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,
where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 7S FARRINGDON STREET, CITY.
Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and eminent makers. —Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments forwarded for 6 stamp

The Medical Circular.

)R. EDWARDS CRISP ON THE SHEEP PLAGUE.

Dr. Edwards Crisp has addressed a letter to the Right onourable the Lords of the Privy Council, in which he us relates his experience of the Sheep Plague :—

I went to Norwich on the 21st of October, and through e kindness of some members of the Cattle Plague Asso- tion, of Mr. Wells, the intelligent veterinary surgeon, l of Captain Lambert, I was enabled to study the ease in the living animal, and to investigate it after ith. I may premise that my frequent examinations of abs and sheep during many years will enable me to ak with some degree of certainty on this question, hough it is one, I admit, that is beset with difficulties. In Mr. Harvey's park at Crown Point, where the oxen d, there were 2,060 lambs, which fed where the cattle ; and after the death of the latter some of the lambs re attacked, and they have continued to die daily ever ce, so that only about 730 are left, and of these probably greater number will perish. The symptoms are at first ness about the nostrils, followed often by muco-purulent charge, redness of the conjunctival membrane, head rn, ears depressed, loss of appetite and absence of nination, dry cough, thirst, frequent diarrhœa, the dis- rge from the bowels was of a dirty yellow colour. The ation of the disease, from the appearance of the first ptoms, is from twenty to seventy hours. Many lambs have recovered lose a part of their wool, as is the in other diseases of sheep where the blood is vitiated the debility great. Of these lambs, I examined at the metery" on the 23rd of October, four ; 24th, six ; 25th, e ; and the 26th, four. In addition to these, I had an ortunity of seeing, through the kindness of Mr. Wells, ring lamb that had been inoculated from the ox, and xamining its viscera after death, as well as the viscera nother lamb that had been turned when in a healthy among diseased sheep ; but the latter cases may be rted elsewhere, so I refrain from further allusion to at present. I append a table of the autopsies of th-three of these lambs. In all I made a very careful ination, and in nineteen I laid bare the whole length ie alimentary canal. I have tabulated the appearance ie eye, tongue, mouth, the lungs and air-passages, t, blood, the various parts of the digestive apparatus ; ancreas, liver, spleen, kidneys, bladder, urine, vagina, is, ductless glands, brain, flesh, and wool. I now give eneral summary from this table. The first and most le change was the distended appearance of the heart l, with dark, shiny, treacle-like, defibrinated blood ; lot imperfectly coagulated, and in only one instance, e the lungs were inflamed, was there fibrine upon the The blood in the mesenteric and other veins was and fluid ; and to show how much this state of influences the morbid appearances, I found that the most eye was bloodless, whilst that nearest to the d had the vessels of the conjunctiva much con- l. The larynx, trachea, and bronchial tubes were ghly vascular, but the vessels, unlike those in ordi- inflammation, could readily be emptied of their blood essure with the finger, leaving the rings of the wind- white until the vessels refilled. This state of blood what resembles that which I have seen in poisoning ussic acid. In this condition of the circulating fluid, ot to be wondered at that nearly all the organs were congestive or vascular state. The brain, lungs, air-tubes, heart, kidneys, and pancreas, were preternaturally full of blood ; but, with the exception of the lungs and kidneys, no structural alteration was present. In eight, the lungs were either in the first stage of inflammation, or partly solifiided by old-standing disease. In three, the kidneys were divested of their capsules, from the generation of gas, an alteration I have seen in many species of ruminants. In all, the liver was more or less softened ; in ten it was granular, and easily lacerable, the finger passing readily into its substance. The gall-bladder was generally distended with bile. The spleen in all was of small size and healthy. As stated before, in nineteen I examined the whole tract of the alimentary tube ; in six, parts only of the canal were inspected. In all, the stomachs were softened, and the epithelial membrane readily peeled off. In sixteen, the fourth stomach was universally red or covered with irregular shaped red spots, less definite in form than in the ox. In five, the fourth stomach presented little or no trace of redness, and the red marking and mottlings of the intestines were indistinct. The cœcum in nearly all was more or less spotted or ecchymosed ; the other intes- tines red in many places, but not generally presenting the same mottled appearance as in the ox. The rectum, near to the anus, in nearly all was congested and streaked with red. In ten, Peyer's glands were of a claret colour, but not ulcerated ; and the red patches in the fourth stomach did not present the same raw appearance as in the ox, the epithelial membrane being entire. In three, lymph-like exudation was present in some parts of the intestinal mucous membrane ; and in one this exudation was confined chiefly to the root of the tongue and to the upper part of the larynx. If I had inspected some of these lambs only, I might have come to the conclusion that the disease was of a doubtful kind ; but a more extended examination convinced me that the disease was "cattle plague," modified somewhat in the sheep, as shown by the mottled appearances I have described. I have witnessed the same condition of the blood in ruminants dying at the Zoological Gardens ; but the erythematous and spotted aspect of the fourth stomach, and the mottled appearance of some parts of the intestinal tube, I have never before observed. In addition to the softened state of the liver in the sheep, the dark and tarry condition of the blood, the general softening of the lining membranes of the stomachs, the absence of red patches on the lips, cheeks, and tongue, the contents of the gastric cavities present a remarkable difference to those seen in the ox. In the sheep, judging from twenty-eight that I have examined, the food in the stomachs is always soft and pulpy, and never presents the dry appearance it does in the ox when affected by this disease. There is another pecu- liarity worthy of note—viz., that, as in the so-called typhoid fever of the pigs, the young appear to be chiefly if not solely affected.

I have not space in this letter to enter into the condition of the lambs at Crown Point, and the nature of their food when attacked, but I may observe, that as far as I can judge, thousands of lambs in England are worse fed and worse cared for, and, notwithstanding this, are in good health. The same outcry was raised about the London cow-sheds ; but it is notorious that the mortality has been as great, if not greater, in some of the most healthy parts of England, as in localities where the atmosphere has been impure and the animals densely crowded. Let me take the parish of Melford, Suffolk, where I spent four years of my pupilage, and to which place I journied from Nor- wich. Besides the well-known losses sustained by various farmers in this healthy district, the cattle in Melford Park, as at Crown Point, were all destroyed, either by disease or by the pole-axe, with the exception of one solitary ox that I visited ; his grave had been dug, but, notwithstanding his helpless and hopeless condition, he cheated the Govern- ment and the inspectors, and there he grazes, his well-filled paunch and sleek coat telling plainly that his vitals have recovered their pristine soundness. If he could speak, my lords, what a lecture he might give to the Govern- ment on their tardiness and supineness in this fearful calamity ?

GENERAL CORRESPONDENCE.

SHALL MACGREGOR HAVE A STATUE?

To the Editor of the Medical Circular.

SIR,—It has often happened that really great men have passed their lives in obscurity, their transcendent virtues unrecognised, their gigantic powers undisplayed, and their works unappreciated.

"Hands that the rod of empire might have swayed" have grown horny in handling the flail, or grimy in the lighter employment of cleaning knives and shoes. . . . What a proud man he has a right to be who has from "the dark unfathomed caves of ocean" fished up the "gem of purest ray serene," brought out the "village Hampden" with the particularly "dauntless breast," or has anthropoglossicized a "mute inglorious Milton."

What a happy, fortunate, much-to-be-envied man, then, must be John James Macgregor, M.D., M.R.C.S.E., of 14 Upper Seymour street, Portman square, W., who discovered the merits of Dr. Robert Hunter; what a generous and disinterested benefactor Dr. Macgregor, of 14 Upper Seymour street aforesaid, must be to have published the letters on "Diseases of the Throat, Larynx, and Lungs—their Nature, Causes, and Cure" (all for the price of half-a-crown, in scarlet cover, set off with white lines), by Dr. Robert Hunter aforesaid.

Shall Cromwell have a statue? Nonsense! Macgregor, M.D., is to have the vacant niche in St. Stephen's, and there shall be no delay about it. Macgregor shall go and see his own statue inaugurated or unveiled. Preposterous? Not at all; why so? Has not Macgregor made known to the British public the name of the man who cures consumption, and is not that the same thing as curing it himself? Dr. Robert Hunter, of New York, cures consumption; at least, he says that he can do so. Dr. Macgregor, of 14 Upper Seymour street, Portman square, "found" Dr. Robert Hunter's "labours had been long appreciated, and had procured for him a wide-extended fame, and an ample fortune in America."

Dr. Macgregor then felt convinced that when the "enlightened and masterly views" of Dr. Robert Hunter, of New York, "on the *origin*, *nature*, and most important of all, *treatment* of diseases of the lungs, became known to an unprejudiced and impartial public," Dr. Robert Hunter, of New York, "would meet the reward he so richly deserves." That reward, since he has secured a wide, extended fame and ample fortune in America, surely need be none other than to see the statue of Macgregor, M.D., of 14 Upper Seymour street, Portman square, wheeled down to Westminster by a team of twenty of Kelk and Lucas's most splendid waggon horses, and duly installed amongst the notables of English history.

Dr. Macgregor has introduced in his unauthorised publication (for he nowhere says that his edition of Dr. Robert Hunter's "Letters on the Throat, &c., &c.," is an authorised one), numerous cases which he deems "especially valuable since they in many instances emanate from members of the Press or the Medical Profession,"—*American* Press and *American* Medical Practitioners of *course*. Probably the imaginative contributor to the American Press who furnished the test of British holders of Confederate Bonds was one of Dr. Hunter's cures. Dr. Macgregor thinks they derive an especial value, "inasmuch as they each bear (*sic*) a voluntary as well as a grateful testimony to the benefit derived from the skill of the physician."

The simplicity of Dr. Hunter's views constitute their great charm. "Consumption," Dr. H. says, "is caused by *tubercles of the lungs*. Tubercles are little granular bodies deposited from the blood. They are most frequently located beneath the mucous membrane of the air tubes, but they are also deposited in the air-cells and on the free surface of the mucous membranes."

What causes the tubercles though?

"Neglected catarrh, sore throat, and bronchitis," which, preventing the free ingress of air to the lungs, interferes with the decarbonization of the blood, and promotes the deposit of tubercles, for "softened tubercle is nothing more than *carbon* united with the elements of the tissues in which it was deposited." Consumption is to be cured, obviously, "by restoring the purity of the blood and causing the oxidation and absorption of the tubercles." What is easier than to make an egg stand on one end when you have been shown the trick.

Inhalation is the secret. "The lungs," Dr. Robert Hunter, of New York, says, "were designed by Nature for the reception of air, gas, and vapour," therefore, by means of vapour we convey medicaments into the lungs, that is, to the very seat of the disease itself. Dr. Hunter says, "because Physicians cannot apply washes and ointments to the inner surface of the air-tubes they desert the principle of direct medication altogether." Dr. Hunter, of New York, is evidently unaware that inhalation was practised in England before, probably, the Medical Profession in America (where he has gained the wide extended fame and ample fortune), received its so fortunate son into its unconscious ranks.

Dr. Hunter laughs to scorn the bare notion that any medicament taken into the stomach can reach the lungs. "How can," he asks, "a medicament, put into a healthy organ, possibly affect a diseased organ at a distance from it."

What idiots English Physicians and physiologists must be!!

I learn that Dr. Hunter, leaving his ample fortune in America behind him, has come to this country. I can cordially join Dr. Macgregor in one sentiment—namely, that he will meet the reward he so richly deserves.

I am, &c., PALMAM QUI MERUIT, FERAT.

OXFORD AS A SCHOOL OF MEDICINE.

The last point on which we have space to touch is Oxford as a school of science. Here, again, all is change and progress. Without any disparagement to those who have promoted the study of physical science in Oxford, from the time of Boyle to the days of Powell, Buckland, and Kidd, it is certain that till after the middle of this century—that is, till fifteen years ago—there was no united, systematic attempt to make science, as such, part of the general education of the Oxford youth, or to provide them with that which is essential for success in it, the means of practical instruction.

When, indeed, some of the Oxford authorities set themselves with seriousness to this task it was no easy one. The Convocation, who hold the purse strings, were not only averse to change in the character of the studies, but were generally unacquainted with the nature of the science which it was proposed to incorporate. They, therefore, honestly, but in too many cases blindly, resisted any attempt to give activity to dormant professorships, or to studies whose worth they doubted and whose influence they feared. A sharp contest ensued between those who, believing in the past alone, dreaded the future, and those who, trained in critical studies, trusted the God of nature to care for His own, assured that He who made preserves, and that His works are part of His Word to man. Slowly the newer conviction worked its way. With that practical sense which our countrymen so eminently possess, two persons, among many others apparently as little likely to aid the movement as could have been named, and who differed in their own theological departments, the Reverend Dr. Cotton (the Vice-Chancellor) and Dr. Pusey, each supported the vote for the erection of the well-known Museum. Thenceforward all went with comparative smoothness. Though every money-vote was pertinaciously contested, still it noiselessly but "slowly the palace grew," and ten years ago a building appeared furnished, according to the several views of the professors, with practical appliances of scientific study, more or less perfect, in most of its departments. Mathematics, astronomy, geology, physics, chemistry, mineralogy, zoology, anatomy, physiology, Medicine found a common home, with a common library of reference, generously provided by the Radcliffe's trustees. I need not, indeed cannot, enter into the details which would be necessary for describing in full the arrange-

nents and intentions of this edifice, where Brodie, Phillips, Tolleston, Donken, Acland, Henry Smith, Westwood, and ther well-known men carry on their instructional or scien-ific labours. I can only say a few words on the scope vhich the institution seems to have in its relation to ational or Medical education.

The authorities of the University appear to have estowed much attention upon the subjects which they hall endeavour to teach, and on which they shall hold ex-minations. They felt apparently that what they under-ook they should strive to execute with efficiency, and what ney could not do well they determined not to attempt. s regards the Medical Profession this principle was of rimary importance. All the discussions that have taken lace in the last few years have served to show more and ore that while our great metropolitan Hospitals could, nder a sound educational system, treat with efficiency all ie practical parts of the art of healing, their success, such s it is, is diminished by the want of early classical and ientific training in the students that flock to them. xford has been aiming to supplement this Professional id national want by reducing the length of residence, by iminishing expense, and by increasing the means of ientific study. What, therefore, it is so improper—ideed, so impossible—to obtain at a Hospital, an educa-on in Arts, and a preliminary rearing in Natural Science, now put, at Oxford, within the reach of those who can are the time for a University course.—'Medical Times id Gazette.'

REVIEW OF BOOKS.

hloroform: its Action and Administration. A Handbook. By Arthur Ernest Sansom, M.B., Lond., late House-Physician and Physician-Accoucheur's Assistant to King's College Hospital. Pp. 192. London: Churchill and Sons. 1865.

r. Sansom, having been frequently associated with the te Dr. Snow in the administration of chloroform, and aving also for a considerable time been in the habit of lministering the anæsthetic at King's College Hospital, id in the private practice of several eminent surgeons, inks, and not without reason, that he may be excused for endeavouring to supply a want," inasmuch as it has ap-ared to him that the time has come when the separate perience and teaching of individuals on this subject may advantageously formed into a truthful and brief com-ndium. We are bound to state that Mr. Sansom appears possess all the necessary qualifications for the task he s undertaken, and the little book he here presents to the ofession seems to comprise a great amount of useful in-mation derived from all available sources, while the ictical rules he lays down for the guidance of those who ploy the anæsthetic are founded upon sound reasoning d no small amount of experience.

The history of the invention of chloroform as an anæs-tic, its great and important services to Medicine and rgery, the dangers occasionally attendant on its use, and precautions recommended during its administration, all subjects which have been so recently canvassed and cussed, that a writer on such topics must occupy beaten und, and his chief claims to notice must rest upon the ngement of his materials or the practical knowledge he ngs to bear in their application. Mr. Sansom's work is ided into chapters, which successively explain the dis-ery of chloroform, the influence of the discovery, chemical nature of chloroform, the effects of its alation, its physiological action, the operation of esthetic agents generally upon the blood and the circula-n, the danger of chloroform and the circumstances which dify the peril, the diseased conditions of the body which rease the danger, the danger of the incautious adminis-tion of chloroform, the signs of danger, the mode of uscitation in apparent death from this agent, the methods dministering it, the value of anæsthetic mixtures; and concluding chapters are devoted to the applications of chloroform in surgery, in obstetric practice, in practical Medicine, and in dentistry.

In the introductory chapter, Mr. Sansom, in allusion to the use of narcotics and sedatives, mentions the curiou fact that the compounds of formyle have been employed for their physiological agency by unlettered peasantry. Chemical readers are, of course, aware that formyle and formic acid are so named from the fact that they were originally derived from *ants* (formica, Lat.), and it seems that crushed ants have been used to allay local pain, and in Norway the common beverage of the lower classes was in former years a spirit, in which a bag of large white ants was boiled and left to simmer. When the ant-bag had remained for an hour or more in the spirit, it was removed, and the intoxicating drink was served out. The effect of this beverage was rapidly to produce a delightful dreamy condition, which soon passed into complete unconsciousness, from which it was impossible to rouse the drinker by loud speaking, or shaking, or pinching. This condition, however, would pass away in an hour or two, leaving the person quite well and without any headache or other discomfort. It appears, too, that surgeons were accustomed to perform operations upon persons on whom anæsthesia had been thus produced, but the facts did not give rise to any further investigation.

We regret that our space forbids us from entering at length upon the various topics discussed in Mr. Sansom's book; but from the great interest attaching to chloroform in the present day, this manual will no doubt find its way into the hands of most of the Profession, to whom we can confidently recommend it as a safe and trustworthy guide.

History of a Successful Case of Amputation at the Hip-Joint. By J. Sampson Gamgee, Surgeon to the Queen's Hospital, Birmingham. Pp. 33. London: Churchill and Sons. 1865.

This interesting monograph relates the particulars of a case in which amputation was successfully performed at the hip-joint for an enormous and long-standing disease of the thigh-bone. The limb measured forty-eight inches in circumference, and when removed it weighed upwards of ninety-nine pounds, considerably more than half the weight of the entire body. The disease originated in an accident in the year 1851, when a piece of coal of about two hundred weight fell on the right foot of the patient, who was a miner in a coal-pit. This occurrence seems to have given rise to enlargement of the thigh of the same side, and in 1860 the measurement of the limb was twenty-nine inches in circumference, and in September, 1862, when the operation was performed, the dimensions increased to those we have above stated. The operation was performed at the urgent request of the patient, but there were other circumstances which justified the proceedings, such as the apparent benignancy of the affection, the temperament, which was placid and resolute, and the fact that there was sufficient of the soft parts to cover the wound after disarticulation of the hip-joint. The limb, in consequence of its great weight, was suspended by a pulley to the ceiling during the operation, and the disarticulation was made without any great difficulty, and a sufficient flap obtained to cover the wound. Eighteen arteries were tied, the femoral being of very large size, and several of the others being also very large. The femoral vein was gaping and thickened with greatly-distended walls, and a ligature was also placed on this vessel. The hæmorrhage had been controlled by the aortic tourniquet.

The patient recovered from the shock rather speedily, but hæmorrhage returned, which was restrained by the re-application of the abdominal tourniquet, and ligatures were applied to the orifices of the bleeding vessels. In little more than a month, the stump had healed, and the man, who was previously emaciated, quickly regained his health and increased nearly 100 pounds in weight.

The subsequent examination of the diseased bone, of which two beautiful photographic illustrations are given, showed that the specimen was one of Ossifying Enchondroma, the lower three-fourths of the os femoris being surrounded by, and enveloped in, the morbid growth.

The case is undoubtedly deserving of record, and is worthily presented to notice in the work before us, for the volume is luxuriously got up, the paper and the type being of the finest description, and the photographic illustrations being executed in the highest style of art. The latter represent the appearance of the patient before the operation, his appearance after it, and the characters of the enchondromatous tumour, which is shown first in mass and afterwards in a longitudinal section.

Cholera; its Pathology, Diagnosis, and Treatment. By William Story, L.K.Q.C.P.I., F.R.C.S.E. Pp. 79. London: E. and F. N. Spon. 1865.

When the cholera appeared in England in 1832, Mr. Story was a student at the London Hospital, and was daily witnessing cases in the Whitchapel and Mile End Unions. He next observed the disease at Jessore, in the East Indies, in 1838-40, and became confirmed in his opinion as to the non-contagious nature of the epidemic, this being the belief of the natives themselves. He afterwards returned to England, and witnessed another attack of the disease when practising at the East End of London. Thus it will be seen that Mr. Story has had considerable practical experience as to the nature of cholera, but we cannot conscientionsly state that he has thrown much light upon either the pathology or the treatment of this unwelcome visitor. The treatment he recommends is eclectic, and he deprecates the use of cold. In addition to the meagreness of the information afforded, the book is very carelessly written.

The Dental Licentiates' Directory and Local List. By Alfred Hill, L.D.S. London: Churchill and Sons. 1865.

Mr. Hill thinks that he is meeting a decided want in proposing to compile a directory, or a list of those gentlemen who have taken the Degree of Licentiate in Dental Surgery of the College of Surgeons of England. This list is the more necessary, he thinks, from the unsatisfactory conciseness of the College list, and he also believes that the knowledge thus offered of one another would be agreeable to the dentist community, and form a stronger bond of union among them than at present exists. Mr. Hill has performed his present task very neatly, and he solicits fuller details from his brethren so as to render the next issue of the directory as complete as possible.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. BARNES continues his lectures "On Puerperal Fever," and having in former lectures considered those cases of this affection which are auto-genetic, or caused by conditions proper to the patient herself, he now proceeds to analyze and appreciate the numerous causes of fever which attack the lying-in woman from without. It has been assumed by some that puerperal fever is mainly caused by elements of infection derived from dissection or from persons labouring under contagious diseases, and carried to the lying-in room by the Medical attendants. It has, therefore, been argued that if obstetric practice were entirely separated from Medical practice, and conducted by females, puerperal fever would be materially diminished. The proofs of this argument are made to rest upon the evidence of statistics, but Dr. Barnes shows that the results do not really confirm the views in question. A comparison is made between the rate of mortality which occurs from puerperal fever in the gross population of London, and that which arises from "puerperal causes" among the patients attended by the Royal Maternity Charity. But there are many fallacies in this comparison, for all the women in the general population are not attended by Medical men, but many of them are attended by midwives. Again, the patients of the Royal Maternity Charity are in a great measure a selected class, for they are all married women, and thus all the cases of puerperal single women, most of whom are primiparæ, are excluded. For this and many other reasons which are adduced by Dr. Barnes, the comparison between the two classes is not a fair one, and the evidence from statistics is not to be relied on. It moreover appears that the records of several hospitals, as of St. Thomas's and Guy's Hospitals, show a smaller mortality than that of the patients of the Royal Maternity Charity, although the patients of the former are attended by Medical men.——Mr. BARNARD HOLT communicates a paper "On Five Cases of Stone in the Bladder, where no Surgical Examination had been made." These cases show that in all instances where the ordinary symptoms of stone in the bladder are present, a surgical examination should be made. The neglect of this proceeding may entail great and prolonged suffering, and when operative interference is adopted, the results may be fatal, as is shown in Mr. Holt's first case.——Dr. HORACE DOBELL, in a paper "On the Assimilation of Fat in Consumption," gives a "Third Report of Cases Treated with Pancreatic Emulsion" at the Royal Infirmary for Diseases of the Chest, City road. The pancreatine and pancreatic emulsion are now prepared by Messrs. Savory and Moore. The effects of the emulsion appear to be in general beneficial.——Dr. J. DANIEL MOORE contributes a short paper "On Respiration and Signs of Life in a Fœtus delivered at about Five Months' Gestation," and he illustrates his remarks by a case which is of interest as showing the very early period at which respiration and pulsation may exist in the fœtus expelled from the womb. Except respiration and pulsation there were no other signs of life; but in a medico-legal point of view, the case is worthy of record in reference to succession or inheritance of property.

THE JOURNAL OF MENTAL SCIENCE, published by authority of the Medico-Psychological Association. Edited by C. L. ROBERTSON, M.D., Cantab., and HENRY MAUDSLEY, M.D., Lond. October, 1865.

The first paper in the present number consists of "Some Remarks on a Recent Attempt at the Comparative Statistics of Bethlehem Hospital, and of the English County Asylums," by Dr. ROBERTSON, and the author of the paper controverts the views entertained by the advocates of the salubrity of Bethlehem Hospital, and argues that there is no excess of cures at Bethlehem over many of the County Asylums.——The next paper is a translation from the German—namely, "the Prognosis in Mental Disease," by Dr. GRIESINGER, of the University of Berlin, who examines the question under two heads—namely, as to the influence of insanity on the duration of life, and on the probabilities of cure in cases of insanity. To the first question he replies that after the acute stage has passed, lunatics may live for a long period, and he examines the second question by considering all the modifying circumstances which may influence the prognosis.——In an article "On Insane Patients in London Workhouses," Dr. F. E. ANSTIE censures in very strong terms the inadequate arrangements made for the treatment of such patients in many of the establishments placed under the control of the Board of Guardians.——Mr. W. A. F. BROWNE, Commissioner in

Lunacy for Scotland, contributes a paper "On Epileptics, their Mental Condition." This paper, which was read before Dr. Laycock's class of Medical Psychology, gives a most able sketch of a very difficult subject, and points out the different derangements or perversions of the mental faculties which epilepsy usually entails upon its victims. ——Dr. T. B. Belgrave contributes a paper "On the Bromides of Potassium, Cadmium, and Ammonium in the Treatment of Insanity," his conclusions being that these drugs exert a certain influence upon some of the more violent cases of mania, and that they in some measure are also useful in cases of general paralysis, and in epileptic patients.

CYCLOPS' TWENTY-SEVENTH LETTER ON PHYSIOLOGY.

To Vigilans.

Sir,—The first point I have to notice where aperients are hurtful in the highest degree is when they are given after parturition. I claim some authority here, as having had above four thousand infants to my hands from their birth, independently of miscarriages. There is not a more important subject in physiology than what I am now about to touch upon, and I am pleased to see a feeling growing up in the practice of Medicine on the subject of the treatment of our women in these cases. I have always considered the practice of low diet almost equal to starving, combined with purging of the parturient female as one of the grossest of errors, and that these cases have been treated more as cases of disease than what they really are—namely, simple natural acts. Therefore, to keep a case of this kind for days after parturition on gruel, and on or about the third day after to purge, is nothing short of a premeditated attempt at manslaughter. In the largest percentage of these cases we have a right to conclude that there is a good condition of health, with a natural act to be performed. It is called "labour," and God knows it often is, and very hard labour too. Suppose a female pressed by some dire necessity to walk twenty miles within a given time, and as a consequence to become perfectly exhausted. She is put to bed and a doctor sent for who hears her story. Would he, knowing her exhaustion from such a source, keep her on gruel for a week or ten days, and order her purgatives? No! He would say let her rest and give her nourishing things. But what has been and is now the general habitual treatment of these natural parturient cases? These natural labours? These simple natural acts of great effort with a call upon all the bodily and muscular exertion of a male in the highest health and condition? I am grieved to say, except with a few far-seeing and intelligent men, that it has been a gruel diet for some days or a week, and then the second or third day purging. What for? Is there disease? No! Is there fever? No! The patient could eat and drink if permitted, but they are forbidden through the grossest ignorance of physiology, to do so. Now, let us look calmly at the fact. A healthy woman is suddenly seized with the pains of child-birth. The first pain almost invariably produces an action on the bowels. As labour progresses, a second may occur, and as the child is passing the outlet, should there be any fæces in the rectum, they are pressed out. Well then, the colon may be said to be empty. Now, I have shown that it is distinctly necessary that it never should be empty for any length of time. I have shown the value of fæces as fæces, from whence the body gets certain gases to resist the oxygen of the atmosphere around and about it. That these gases are necessary to form fluids as well as to keep up the plumpness of the body, and not only this but brain power from the phosphorous, that they also eliminate with the hydrogens. Now, how long does it take properly to fill the colon under the natural circumstances, of which I have been speaking? Why, several days under the best diet of meat once a day, and the satisfying supporting fluid of malt and hops, but when the colon is sufficiently filled, and the fæces sufficiently abundant to make their gases, an ejectment of the excess as naturally takes place as that pigs squeak, or any other natural act. The consequence is, powers are restored in their natural way, and we have what is called a good "getting up." Milk is formed in sufficient, even superabundant quantities, and Nature, in all her beautiful laws, is triumphant. On the other hand, what do we see? Why, the female starved upon gruel and bread and butter and tea. What a sorry fare to make fæces upon! Yet they are made to a certain extent, but of very poor quality, nevertheless. But on or about the third day, a dose of castor oil is administered. The doctor orders it, and the more ignorant nurse follows the advice promptly, to do what she, in her capacity says, "to cleanse her." To cleanse her from what? She believes to cleanse the womb. God save the mark! for I verily think some doctors believe so too. So that, with only this insufficient diet, while Nature is trying to abstract power even from the poor mass formed, even that is to be carried off. I do not think ignorance can go further. What is the result? Utter prostration of power, and little secretion of milk, and when this has lasted a week, some beef-tea may be ordered, but the poor patient getting low, a little brandy may be given. Then it is wondered how a strong, healthy woman, who before the natural act of parturition, which has been performed in a natural way, should be so low and prostrate. No wonder we see those melancholy facts under the head of Births, Marriages, and Deaths—viz.: On the 1st inst., Mrs. —— of a son. In a week or ten days after, Died Mrs. ——. What a pity this episode could not be completed by adding, "from starving and physicking, after a natural parturition *secundum artem*." It has been my lot to have been called in in consultation in many cases of great danger after parturition, from the sole cause of the patient's having been kept too low, and I have pointed this out to the gentlemen in attendance, and warned them against this very absurd plan of treatment.

They say they are afraid of inflammation, or of milk fever! Why, the lowering plan is the very best in the world to produce these evils. It is of no avail that some members of the Profession occasionally bring forward the fact of keeping our parturient women too low; they state these circumstances as the simple result of their own observations. If they were accompanied by a philosophy, such as I have set forth, they would make greater and more lasting impressions. Parturition is not disease, and therefore, there is no reason or common sense in these cases being treated beyond the first day by slops or gruel, when a daily chop after the first day would be more support, and if not accompanied by a glass of porter, this may be added the third day with advantage. When fæces of sufficient quantity and quality have been made, Nature will always get rid of the superabundance by her own laws, and a few days conservatism will do more good than harm. It is more in accordance with all natural and physiological laws. All these matters I have now advocated for more than a quarter of a century.

The next cases where conservatism of the colon is seen to be a natural seguitur is after heavy falls, blows or contusions. Nature immediately after these, requires all the powers she can collect from every source, and none more than from the gaseous elements eliminated from the fæces. Again, from severe burns, she shows her wisdom in this act. Last year I had a case of a brewer's apprentice, who fell into boiling liquor up to his middle. He was enabled to lift one leg up, which was consequently not so much scalded; the other, to above the knee, was in a frightful state, so that in pulling off his trowsers and stockings the whole mass of skin came away. In order to relieve pain, I dressed his legs for forty-eight hours with the beautiful and well-known preparation of equal parts of linseed-oil and lime water. After this, I put his legs into a mass of wheaten flour, excluding the air entirely, and dressing them once a day. The discharge from the most injured limb, as is usually the case, was enormous, forming with the flour great cakes, all of which were carefully removed by the spatula, and the leg again put into the flour, and flour applied thickly by the dredger to the upper portions. I gave him opiates, and

kept his bowels confined for a fortnight. This, with good and generous diet, as soon as he could take it, the limb recovered most rapidly without any aperients. Nature dictated the removal of a large consistent motion in her own due time, and in four weeks the whole limb was perfectly restored, the new skin only showing a little redness. I attributed the rapidity of the cure and fresh formation of the new parts entirely to the conservatism of the colon and the vital forces and powers gained therefrom.

In all operations, the very first thing that should be done by the physician and surgeon, is to conserve the bowels and follow what Nature is sure to be the first to do. This I have already spoken of in mentioning the circumstance of a friend of mine, communicating this point of physiology to Mr. Baker Brown after the operation of extirpating abdominal tumours. All these matters relate to cases where accidents or other circumstances occur in a hight state of health.

Now, the Faculty, as a body, do the very reverse. Their first question is—Are the bowels open? If not, they set about opening them directly, and keep them open against all philosophy.

On the other hand, let us consider how Nature deports herself in certain diseases. In fevers for instance, the fact of constipation setting in coincident with them, seems so glaring that, the only wonder is that those who have had the greatest experience in their treatment and who must have seen this, that they have not looked upon it more as a law than for a reason for opposition. It is now twenty-five years since I first noticed this fact and willing to watch all natural laws, I let a case go on and while I did not interfere it did well; but the mother being alarmed at a conservatism of twelve days, injudiciously followed the advice of a sympathizing friend and gave a dose of castor-oil. This produced an action on the bowels which was followed by delirium and nothing that art could do, was able to prevent a persistent diarrhœa and in consequence the patient died. I asked her if she had given any aperient, she said No! I taxed her again with it, she still denied it. But when her child was dead, I again asked her to tell the truth, feeling assured, it had been done and she confessed to the fact. Nevertheless this was an advance. In subsequent cases I took better precautions and my success in following this plan has been well rewarded; yet how unsatisfactory to science, to know a fact and not its cause. All these circumstances have been followed up step by step until I am now prepared to state that which I have in these letters relative to the value of fæces as fæces and that we owe to the colon and to the fæces themselves the best vital powers and principles of our bodies. Where a fever, seizes us, which is to the body the same as a drought to the earth, all our streams and rivers, seas and lakes, ponds, canals and rivulets become dried up. It seems of no avail to proffer the jug of pure water to drink, or to apply the sponge with its delicious moisture to the surface of the body, all is soon absorbed and dried up. Where are we to look for the return of all these inward waters of life. The body is scorched and it withers, for Nature herself failing to make her own fluids, an annihilation appears imminent. All the moisture, through the whole extent of the primæ viæ and the colon, becomes absorbed. When this is done, robbery and felony succeeds everywhere; the two great currents of blood in the arteries and veins must now yield all they can. No glands can act, for they are already impoverished. If the blood furnished them with their secretions, why does it not do so now? Cannot physiology see even in this, that it can only furnish structure? To add to all this evil, the faculty must step in and unwisely administer aperients, but they get nothing by them but evils. Where is the moisture to enable fæces to pass? They get little or none, probably only a little coloured matter which they have forced out *vi et armis*. But, if the bowels are allowed to remain constipated, hydrogen from the fæces may yet be generated and combining with the oxygen, that natural moisture which the body requires, is gradually restored and with it all natural streams and rivers. No wonder the Profession take credit for a negative and say they treat fevers better now-a-days, because they leave them alone to Nature. She conserves the colon and the fever then abates. As soon as it begins to do so, a firm, healthy, solid stool is the result, surprising everybody. A stool such as the healthiest individual delights to pass. Therefore it is in fevers we see the true value of conservatism and it was from fevers I learnt my first lesson in the true physiological uses of the colon.

Again as regards headaches, it is supposed that these are produced most frequently from constipated bowels. Well, so they are occasionally, but it is from this fact that so many errors have arisen, because no physiologist has ever pointed out that they are also produced from relaxed bowels and what is more, more agonizing and painful ones. People may be heard to say, "if my bowels are not open, I have a headache," but no one ever attributes a constant headache amounting almost to a specific disease to their bowels being too much relaxed. There is no greater mistake made than by writers on cerebral subjects who have advocated the persistent use of aperients in persistent headaches. Did it never occur to these men that a headache might arise from a deficiency of structural brain elements or alimentary brain power, as from excess of either. I tell them that headaches arise oftener from the former than the latter, and that these are of that class which are the most difficult to be endured. Yet I never knew an instance of both that the same plan and treatment by aperients were not prescribed. I have spoken in a former letter of the sympathies of the colon with the cerebrum or reflecting portions of the brain and of the stomach and chylopoietic viscera with the cerebellum or the instinctive or animal portion. In papers such as these, I have no time to enter into the minutiæ and treatment of these subjects. These letters are only designed to rouse thought on the subjects touched upon. Neither can I enter now upon the diseases and morbid conditions of the colon and show the wonderful mistakes that the Faculty have made in their utter neglect of the physiology of this viscus and so overlooking and mistaking diseases therein, but attributing them to some occult disorders in more contiguous organs which were all the while perfectly healthy. I must, therefore, be content to say that these shall some day have their due consideration and exposition at my hands. Having opened this subject, I must leave it in order to consider some of the remaining organs of the body such as the glands, the liver, the kidneys, fat, &c., &c., which are very important, and which I will commence with in my next letter.

I am &c., CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

LORD HENRY SEYMOUR'S BEQUESTS.

The late Lord Henry Seymour left about 60,000*l.* to be divided among the "Hospices de Paris et de Londres," and a question was raised as to the meaning of the word "Hospice." A judgment on this point has been delivered in the Rolls Court, which is altogether adverse to the claims of our "Hospitals" as now constituted. The following is the judgment:—Wallace *v.* the Attorney-General. (Before the Master of the Rolls.) "His Honour again gave a judgment in this case, which has come before the Court in various forms as to a bequest in the will of the late Lord Henry Seymour of a sum of about 60,000*l.* to the charitable institutions of London. The will was made in France and is written in the French language, the passage causing the controversy being 'Aux Hospices de Paris et de Londres.' The question the English Courts have to determine is, what institutions are included under the words 'aux Hospices de Londres?' After examining a number of French definitions of the word 'hospice,' his Honour held that such word, and the gift covered by it, did not include 'Hospitals' as generally understood in this country, but must be confined to such institutions as gratuitously received within their walls and permanently provided for persons incapacitated from taking care of themselves, either from old age combined with poverty, or neglected infancy,

or mental incapacity, or from bodily ailments not susceptible of cure. Such a gift did not include such Hospitals as discharged their patients when cured or when incurable, such as Bartholomew's and St. George's Hospitals; or hospitals merely for instruction such as Christ's Hospital; or Hospitals merely for the relief of sickness, and not admitting inmates, such as Dispensaries. The gift must be construed and confined, strictly within the meaning of the French word 'hospice,' and the various claimants must be marshalled accordingly."

A NEW MODE OF EFFECTING DELIVERY.

Although the various measures in which consists what M. Senn, of Geneva, calls his method, are to be found described in all works on obstetrics, yet their simultaneous application is in reality a suggestion which originates with M. Senn. The question of prior invention is here, however, of no import; the system is a sound one, and we conceive it our duty to make it known. The following remarks on the subject, by the learned practitioner we have named, are borrowed from the pages of the 'Revue de Thérapeutique.'

This method, adopted of late years by M. Senn, and which appears to him to afford all desirable security, is founded on practical experience and logical induction, and is a combination of three elements:—

Injection into the placenta of the blood contained in the cord, and of the blood of the infant; gradual and permanent pressure of the abdomen by means of a very simple bandage; and entire immobility of the mother in the horizontal attitude for two hours after delivery.

As soon as the child is born, the accoucheur grasps the cord at about an inch from the navel, in order to protect the latter from any injurious dragging, and with the finger and thumb of the other hand forces back into the placenta the blood contained in the funicular blood-vessels.

By pressure with the finger and thumb, the blood is thus forced back and retained in the placenta, while the fingers of the other hand are loosened, and allow the arteries of the funis to fill. The operator then again presses on the cord near its insertion at the navel, and the injection is repeated with the other hand. This procedure should be renewed three or four times, according to the condition of the child, its more or less plethoric appearance, its screams, &c. Of course, in the case of an anemic infant, this plan should never be attempted.

In every instance, Mr. Senn performs this little operation as promptly as to prevent the mother being aware of it. When the injection has been completed, and the placenta is filled with blood, a ligature is placed on the cord between the vulva and the fingers of the surgeon. It is then divided half-way between the umbilicus and the nature, the child is removed, and the cord secured as usual.

Thus, artificially tumefied, the placenta becomes incapable of following the retraction of the womb, its attachments are necessarily loosened, and the process of delivery is restored to its most desirable conditions—viz., the simultaneous expulsion of the infant and of the afterbirth. If the organ is retained more than five or six minutes above the vulva it can easily be removed by gentle traction.

The second measure advocated by M. Senn is the permanent and gradual compression of the abdomen. The pressure is not effected with the hand, but with a soft cloth in several folds, previously laid under the woman's back in the early stage of labour.

During the progress of labour," says M. Senn, "the extremities of the cloth are folded under the mattress.

"Immediately after the birth of the child, I rapidly ascertain the situation and size of the uterus, and wrap one side of the cloth round the abdomen, while the nurse draws the other extremity horizontally towards her in order to support the abdomen, to give a fulcrum to the muscles and maintain the womb in its position.

"The nurse then hands over to me the extremity of the cloth which she previously held, and with this I again envelop the abdomen. The tightness of the bandage should be gradually increased in proportion as the size of the body diminishes, first on the expulsion of the afterbirth, and again after an interval of half an hour, when it should be permanently secured with pins. This dressing prevents all displacement or dilatation of the uterus; the viscus can neither rise in the abdominal cavity, nor be distended by coagula, and internal hæmorrhage becomes impossible, on account of the permanent pressure, which forms an unconquerable obstacle to its occurrence.

"The venous circulation is also thus promoted by the support given to the body; the circulation in the venous system is rendered more active, and the chances of syncope are thereby greatly diminished."

With regard to the third measure recommended by Dr. Senn—viz., perfect immobility in the horizontal attitude, it is imperatively required by the necessity of avoiding any cause likely to disturb the first fibrinous coagula, which fill the vagina and prevent unnecessary loss of blood. The head of the patient should lie as low as possible, and for two hours after the conclusion of labour, she should drink from the sucking-bottle, so as to render all muscular effort unnecessary.

If, after an interval of eight or ten minutes, the placenta is not found lying in the vagina, M. Senn conceives that it must be attached to the womb by morbid adhesions, and its removal should at once be attempted. But even under these unfavourable circumstances delivery will always be effected in less than a quarter of an hour after the expulsion of the infant, and all danger of flooding will have been averted.

VILLAGE HOSPITALS.—The following letter by Mr. Horace Swete, Surgeon to the Wrington Village Hospital, has appeared in the 'Pall Mall Gazette.' Mr. Kinglake's letter and your remarks on village hospitals have excited so much interest in this subject, that I venture to send you some more information about it. The village hospital system was commenced five years since in Cranley, Surrey, by the united exertions of Mr. Albert Napper, the surgeon of that place, and the Rev. Mr. Sapte, the rector. It was warmly taken up by and advocated in the Medical papers. A very interesting account of it will be found in Dr. A. Winter's "Lissom Fingers and Subtle Brains," which I think was a reprint from the 'London Review,' with a woodcut of the first village hospital. Several Medical men, myself among the number, followed Mr. Napper's good example, and I believe there are now about twenty village hospitals on the Cranley model, though perhaps with slight differences and improvements suggessed by the local requirements. The Wrington Village Hospital, opened in July, 1864, contains only six beds, in which twenty-four patients have been treated during the first year of its existence; there are no out-patients, as this is not entirely consistent with the principle of village hospitals; though at "Honiton on the Water" a village hospital, under the care of Mr. C. Moore, has been in operation four years, where giving advice to out-patients has been found to work well; this, however, would not be the case in most country villages. The village hospital is simply a receiving house for patients with a good nurse—the village doctor undertaking the treatment, assisted by his Medical *confrères* in neighbouring villages. At Wrington the beds are at the service of any medical man in the vicinity, so that an operation or difficult case may be treated by them without losing their patient or their credit, and with more chance of success than in the overcrowded poor man's cottage. From my own experience, and the published reports of other similar institutions, the cost of starting a village hospital is 100*l.* and of keeping it up 100*l.* per annum, exclusive of the weekly payments of patients, which range from 3s. to 6s. per week, according to their circumstances. I send you a report of the last year. I have no hesitation in recommending it to the clergy and Medical men as an excellent work, and a greater boon to the hard-working country doctor, to have his bad cases near home, than even to the poor patient who is benefited.

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause thereof, and have made such arrangements as will prevent the possibility of a repetition of the same. Any gentleman not having received his copy as usual during the last three weeks, will be kind enough to intimate the same to the Publisher.*

WEDNESDAY, NOVEMBER 15, 1865.

THE MEDICAL CIRCULAR.

THE REPORT OF THE COMMISSIONERS ON THE CATTLE PLAGUE.

The Commissioners, who have been sitting upon the subject of the Cattle Plague for several weeks past, issued their first Report on Saturday, and we publish an abstract of this document in another part of our Journal. It will be seen that the Commissioners do not regard the disease as a new one, for a plague of cattle appeared in this country as early as the years 1348-9, and in several subsequent years though at long intervals, and an order in Council in 1746 declared the cattle disease to be of an incurable nature, and framed regulations to prevent its spread.

The Commissioners are all satisfied as to the contagious nature of the disease, and they also admit its identity with the Rinderpest of Germany, and the cattle murrain of Russia, and they conceive that the contagion is extraordinarily swift and subtle. They are, therefore, unanimous as to the danger of permitting the continued circulation of live stock in the United Kingdom, but they are not agreed as to the means which ought to be adopted to prevent it.

The majority of the Commissioners, it will be observed, recommend that the Government should have the power of suspending the movement of cattle from one place in Great Britain to another, and this measure they consider indispensable to the eradication of the disease; but a minority of the Commission object to this recommendation as impracticable, however much it might be desirable to carry it into effect. They think that such a step would involve an interference with trade at variance with our national habits, and produce inconveniences as great as those it is intended to obviate.

As the so-called homœopathic treatment has been declared in some of the newspapers to have been attended with success, the Commissioners have expressed their readiness to test its efficiency, and we are glad that such is the case, for it is a very common allegation on the part of the homœopathic fraternity against Medical practitioners, that the latter refuse even to hear the arguments adduced in favour of the operation of infinitesimal doses, and that they, therefore, wilfully blind themselves to the reception of truth in therapeutic doctrines and practice. That such an accusation is untrue it needs no argument to prove, and the fact is that the homœopathic system has been tried over and over again in the wards of hospitals, and has failed to induce unbiassed observers to believe in its efficacy. Now that the Cattle Plague has visited this and other counties, and its pathology and treatment are alike open to discussion and to doubt, the homœopathic professors again put in their claim to a hearing, and boldly declare that they have found a remedy for the mysterious plague which is raging among our flocks and herds. That the homœopathic, or in other words, the do nothing system, is quite as good or better than the treatment by the pole-axe is quite conceivable, but at any rate the Cattle Plague Commissioners have, as we think very properly, consented to inquire into the merits claimed by the homœopathists. However much we may condemn the trifling with human life, of which we consider the disciples of Hahnemann to be guilty, we can have no possible objection to the trial of their system upon oxen and sheep, and if their treatment should really prove to be as successful as they assert it to be, we shall be among the first to admit the fact, on the principle "fiat justitia, ruat cœlum." We might also add "fiat experimentum in corpore vili," and if the experiments on bullocks and sheep should throw any light on the treatment of human disease, we shall welcome the discovery without the slightest hesitation.

POOR-LAW MEDICAL REFORM.

We mentioned last week that the time had now arrived when the question of Poor-law Medical Reform may be said to have assumed a new phase. Hitherto the subject has been beset with difficulties owing to the utter apathy with which any matter relating to the welfare of the Poor was received by the public. It seemed to be generally thought that the poor were utterly undeserving of the slightest sympathy, and the condition of the pauper was regarded as infinitely inferior to that of the felon. While the latter was tenderly provided for by a paternal Government, and the moral obliquity which rendered him obnoxious to the peace and welfare of society, was treated as a disease; the pauper, on the other hand, was the outcast of the world, and his sorrows and his diseases were almost looked upon as crimes. Hence, while the felon was lodged in spacious, airy, and clean apartments, and his food was supplied to him, excellent in quality and abundant in quantity; the miserable pauper was, on the contrary, confined in miserable, ill-lighted, ill-ventilated dungeons, under the name of workhouses, where he was exposed to every petty tyranny which his task-masters, the local Guardians, might choose to inflict. The Medical Officers, who were almost the only human beings who showed any sympathy for these helpless creatures, were treated by the Guardians (perhaps on that very account) with the utmost indignity; their salaries were, and are, curtailed to the lowest minimum, while their duties were augmented; and what was worse than all, when anything went wrong, they were made responsible for the errors of their superiors, and became the scape-goats of the vicious system under which they held their appointments.

Now, however, the times have changed, and it is almost ıdicrous to observe how the organs of public opinion are ɔeginning to discover that the pauper is not only a human ɔeing, but a constituent element of modern society. For-ıerly the death of a pauper, or of a hundred paupers, nder whatever circumstances of neglect or ill-treatment, ever excited a word of comment, far less of sympathy; ıt now we find almost daily in the columns of the urnals some story of alleged Poor-law misdeeds, and even ading articles in condemnation of the present working of e Poor-law system. The authorities of the Poor-law Board, ;ain, after having been reviled as the supposed friends centralisation and the opponents of local Government, ıve become the protectors of the poor and the severe stigators of the local Guardians, and the very power ıich they wield is invoked as a shield of defence to guard e weak against the strong. Even the wretched tramps ıo migrate from town to town, seeking admittance for the ght at one or other of the workhouses, are all at once vated in the scale of humanity, and the refusal of the al officials to dole out to them the scanty boon of straw l shelter, is censured with a stern rebuke from the lips a Poor-law Inspector.

This very week we find the leading Journal devoting a g article to the sanitary condition of the Bermondsey ɔrkhouse, the defects of which have been lately exposed, l in the same Journal we find a letter from the Medical icer of the Workhouse in question, defending or rather liating the misdoings of the Guardians, and there is yet ther letter by the author of the Report of the 'Lancet nmission by way of rejoinder to the statement of the dical Officer.

Now, whether the Bermondsey Workhouse is as bad as it epresented to be, or whether it is any worse than many ır establishments of the same kind, we know not, but ɔoint to the publicity that such matters now receive as ɔof that the whole system of Poor-law mal-adminis-ɔn is now being fully exposed, and that among the ges which may be anticipated in legislation for the , the condition of the sick poor will receive its due of attention, and the claims of the Poor-law Medical ɛrs will at last be treated with the respect and courtesy h have hitherto been denied.

THE CASE OF DR. ROBERT HUNTER.

shall not, we hope, be considered as advising any-derogatory to the honour of our Profession in ɜting our readers to suspend their judgment in the Dr. Robert Hunter, until after he has been heard in fence. Of his advertising schemes and speculations ve nothing favourable to say, and, on the contrary, we nce them as unworthy of any Medical gentleman ɛspects himself or his Profession; nor do we justify ı assuming a title to which, in this country at least, Acts of Parliament are worth anything, he has no ight. But it does not follow that because a man is of unprofessional conduct, and because he is not recognised as a physician by the laws of Great Britain, he is therefore guilty of a rape; and we have too often noticed the facility with which such charges are made, not to scrutinize very closely the motives of those who make them, and the evidence by which they are supported.

REPORT OF THE COMMISSIONERS UPON THE CATTLE PLAGUE.

The first report of the commissioners on the cattle plague was issued on Saturday afternoon. After a few preparatory remarks upon the purpose of the commission, the report states that the disease was first observed and recognised in Great Britain towards the close of the month of June. Two English cows had been purchased on June 19 in the Metropolitan Cattle Market by a cowkeeper residing in Islington, in whose shed they were when the symptoms of disease attracted, on the 27th, the notice of the veterinary surgeon in charge. Similar symptoms of disease were observed on the 28th by the same surgeon, in a cow belonging to a dairyman in Hackney, which had been purchased in the same place, and on the same day. Two Dutch cows in a Lambeth shed, likewise bought in the market on the 19th, were attacked on the 24th. The malady broke out immediately afterwards in many London dairies, and spread with extreme rapidity, destroying great numbers of animals. The Islington cowkeeper lost her whole herd of 93; she afterwards bought more, and lost them also, making 106 or 107 in all. An inspector, who had charge of a great part of the north and north-east of London, states that in his own district more than four-fifths have either died or been slaughtered, and the general average within the precincts of the metropolis is probably at least as high. Very early in July it appeared in Norfolk; a little later in Suffolk and Shropshire; then in one county after another, and before the end of the month it had invaded Scotland. In all the earlier cases, at least, it seems to have been directly traceable to purchases made in the Metropolitan Market; but Norwich Hill, and other country markets, speedily became in their respective districts, subordinate centres of infection. On the 14th of October it had extended to twenty-nine counties in England, two in Wales, and sixteen in Scotland, and was still advancing. From the Metropolitan Market the disease appears to have crossed the sea to Holland with some Dutch oxen which had been shipped from Rotterdam to London, and had been exposed during three successive market days, and, not finding a sale at an adequate profit, had been re-shipped from London to Rotterdam.

The commissioners come to the conclusion that the disease is contagious, and that the contagion is extraordinarily swift and subtle, being most destructive in its effects. They also conclude that it is the same disease as the Rinderpest, or steppe murrain, the symptoms during life, the results of *post-mortem* examination, and the whole train of general characteristics leading them to that conclusion. Nor is it the first time that the disease has made its appearance in this country. As early as 1348-9, after the Black Death had produced great mortality among men, a grievous plague attacked cattle, which perished by thousands. Again, at long intervals, in 1480, and in 1715, '45, and '57 it decimated our heards of cattle, and appeared to have taken deep root in the country. A commission for Middlesex was appointed on Nov. 25th, 1745, to inquire into the disease, and they appointed cowkeepers and butchers as inspectors of cattle, and instructed them, among other things, "to certify to the destruction of cows, for each of which the Treasury gave 40s." Orders in Council, of a very rigid nature, were issued; and in 1746 one of these orders declared the disease of "an incurable nature," and framed regulations to prevent its spread. In 1757 an Act was passed declaring "that sales of cattle should only take place when the seller had had them in his possession forty days;" calves not being allowed to be sold, in order that they might be preserved for breeding purposes, and severe restrictions were put on the sale of the hides of diseased animals. Various orders were issued stopping local fairs,

and the plague, in consequence of these orders, was extinguished where the local authorities acted with vigour, but lingered in other places, whence it spread, after a time, as rapidly as ever.

The recommendations of the commissioners for the suppression of the disease are six in number :—

1. They recommend that Government should have the power to suspend for a limited time the movement of cattle from one place in Great Britain to another; that they should extend or shorten such period, and renew the prohibition as often as circumstances may render necessary. —1A. the commissioners suggest certain regulations as to cattle traffic, should recommendation one not be adopted. These, they believe, are the only means to eradicate the disease, and that the end fully justifies the means suggested :—First, for a period to be fixed, and which might, if necessary, be extended, no lean or store stock should be permitted to be sold at any fair or market; and sale of such stock by auction or advertisement, or in any other manner whatever, should be prohibited. Second. Cattle might be moved for immediate slaughter to a market, or to a slaughter house licensed for use, but only under a license for transit granted by the magistrates in petty sessions. The license for transit should certify to the healthiness of the district from which the cattle came. With this exception, the transit of cattle over any public road should be prohibited. Third. Precautions should be taken that every animal sold for butchers' meat be slaughtered within a short and fixed period. For the convenience of this purpose no slaughter house should be used without a license from the local authorities, and no such license given except on the butcher undertaking to have all cattle which may be sold or consigned to him driven direct to the slaughter house or premises attached to it, whence they are not to be removed alive. Cattle sold at a fair or market should not be allowed to leave the precincts of the borough, or other place where the fair or market is held, alive. To insure this object it might be required that cattle entering a fair or market should be branded on entrance, and cattle sold elsewhere to a butcher similarly marked at the time of sale, and that it should be penal for any one but a butcher to have a marked animal in his possession. In every place where a public market is held lairs should be provided, in which unsold animals could remain from one market day to another. Fourth. It would be desirable to draw some distinct line between infected and uninfected districts, so that whenever a case of infection is discovered the district should be "proclaimed" as infected in the 'Gazette' and the country papers. The egress of cattle from a proclaimed district should be strictly prohibited, but cattle slaughtered within it, and certified by the inspector to be fit for food might be sent out of it under proper safeguards for disinfection. Provision should be made for enabling districts which had been proclaimed to be publicly set free on proof being furnished that all risk from infection was at an end.

2. The commissioners are of opinion that the power to seize and slaughter vested in inspectors by the Consolidated Order may properly be withdrawn; or that, if retained, it should be exercised only in cases where the inspector's directions as to the separation of sound from diseased stock &c., or any general preventive or sanitary regulations issued by the Government are not complied with. This power is right and useful when the disease has appeared only at isolated spots and attacked a few animals; the public benefit is then very great, and the private sacrifice very small; but in proportion as it extends the hope of thus arresting its march diminishes, the inevitable waste increases, and the sense of hardship tends to become insupportable. In principle a system of compulsory slaughter should be complemented by a system of compensation, and the objections to promising compensation to individuals out of the public treasury on an extensive scale appear to us insurmountable.

3. As regards foreign cattle, the commissioners state that should their first recommendation be entertained, and an absolute embargo placed on all traffic in cattle witthin Great Britain, they think that imported cattle should be slaughtered at the ports of landing. They are further of opinion that cattle should be allowed to land at certain ports only, were proper facilities can be afforded for inspection and transport. In the other alternative, it will be sufficient to say that foreign cattle, if passed by the Customs' inspectors, and not coming from an infected district, may be sent by railway to any market in Great Britain, but shall be then subject to the same regulations as British cattle.

4. During the period of prohibition, whether absolute or limited, the commissioners suggest that no cattle should be allowed to be turned on common or uninclosed land.

5. The commissoners suggest that steps should be taken for obtaining periodical returns of the horned cattle and sheep within the area of every parish in Great Britain, and of their sanitary condition, with especial reference to the present disease.

6. The commissioners deem it their duty to make some reference to the peculiar circumstances of Ireland. The disease, they state, has not yet broken out in that country, therefore there is no necessity for the measures which have been recommended in Great Britain. It is still possible, by the adoption of suitable precautions, to avert the calamity from Ireland altogether. The importation of cattle into that country has been already prohibited for someweeks past. Considering, however, the destructive character of the disease, it will not be judicious to rely upon that precaution alone for escaping it. The evidence which has been laid before them leaves little doubt that it can be conveyed by persons who have been in contact with infected animals, as well as by the animals themselves. In case it should by any accident be carried over, the Government should be in readiness to eradicate it from any spot in which it may appear; and unless preparations are made for doing so before the plague shows itself, the authorities will hardly be in a condition to act with the necessary speed and vigour when the emergency arises. In Prussia, upon whose eastern frontier the disease frequently appears, a system of precaution has been adopted for stopping its further progress which has hitherto met with invariable success. It would probably not be difficult to make provision for the application of similar measures to Ireland, and so to secure to it a permanent immunity from the calamity under which Great Britain is at present suffering. But the extreme rapidity with which the disease spreads makes it important that all arrangements for stamping it out in case of its possible appearance, should be made without delay.

A separate report, signed by Earl Spencer, Viscount Cranbourne, Mr. Read, and Dr. Bence Jones, is appended, stating that these commissioners are unable to join the other members of the commission in recommending the total stoppage of all movement of cattle in Great Britain. If such a measure was practicable, they say it would be more effectual than any other in extirpating the disease. But they do not believe it to be practicable. It would involve an interference with the course of trade at variance with our national habits; and it would demand sacrifices from large numbers of people, who are removed from the presence of the disease, and who will, therefore, not see the necessity for so stringent a measure. The sudden transformation of the enormous cattle trade, by which the large towns are supplied into a dead meat trade, would involve difficulties and dangers of the most formidable kind. The foreign trade, which at this moment furnishes a considerable proportion of the meat consumed in the large towns, would also be seriously interfered with. The price of meat would, in consequence, rise materially, and suddenly these difficulties would lead to the evasion of the prohibition; and if it is largely evaded, as they think possible, it will become then useless.

Earl Spencer and Mr. Read are, however, of opinion that store animals may be permitted to move from the farm of the seller to that of the buyer, provided they have a certificate from a justice of the peace, acting in the district where the sale takes place, showing that they are free from disease, and that they have been located for a certain time on the farm of the seller.

There is also a separate report of Mr. M'Clean, who is opposed to the interference with the traffic in cattle; and who states that the evils arising from it would be greater than those arising from the disease itself.

On the subject of preventive and medical treatment the mmissioners have received, both from this country and om abroad, discouraging but decided evidence that all ethods hitherto adopted have been found unsuccessful. evertheless, being of opinion that Medical science may ill be able to discover agents capable of mitigating the rulence of the malady, the commissioners have drawn up scheme of investigation into the nature of the disease, and ve intrusted different inquiries to scientific men of great ill and ability, who will make reports on the subjects trusted to them at the earliest possible moment.

In the meantime a few sanitary suggestions are offered, hich are calculated to be useful to farmers and dealers in ttle. These may be divided into the following heads :—

I. The general precautions which should be taken by ttle owners to prevent the spread of the disorder.

II. The special precautions required when the plague is the neighbourhood.

III. The measures preventive and remedial, which should taken when the plague breaks out in a locality.

IV. Measures for disinfecting sheds and cattle which have en infected.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

DR. BARNES, PRESIDENT.

WEDNESDAY, OCTOBER 4TH, 1865.

DR. PRIESTLEY exhibited a variety of medicated Pes-ies and Suppositories which he had been requested by manufacturers, Messrs. Duncan and Flockhart, of inburgh, to show the Society. They had been made at suggestion of Professor Simpson, with the view of ad-nistering a diversity of drugs by the vagina and rectum. e vaginal pessaries were so far new that they were of a rvenient Minie-bullet form instead of round, of cocoa-t butter, which readily melted at the temperature of the dy, although perfectly hard before introduction.

Dr. GREENHALGH recited a fatal case in which Cæsarean ction had followed the use of the Cephalotribe. A com-ttee was appointed to examine the effect of this instru-nt upon the fœtal head. The report of the case and of committee will appear in a subsequent number.

The PRESIDENT laid before the Society the original phalotribe of Baudelocque, which had been presented to Society by Madame Petitjean, of Paris, through the ghtful mediation of their Hon. President, Sir Charles ock.

r. BARNES also exhibited a specimen of Fallopian psy.

r. BAKER BROWN, jun., exhibited a preparation of two s of Chloroform with one of Alcohol, to which the dis-d essence of Eau de Cologne had been added, which he found to allay the pain of labour without complete sthesia, and recited cases in which it had been used.

r. BARNES exhibited an instrument made for him by ss for introducing the perforated laminaria-tents into ervix uteri.

. WAY read a case of Twin Pregnancy, in which one of œtuses had died at about the fourth month of intra-ne life, but was expelled at the same time with the , nearly at full term.

. J. BRAXTON HICKS, at a former meeting, read a case

EXTRA-UTERINE FŒTATION,

hich he had detected a fœtus alive in the recto-vaginal a of peritoneum. Considering its advance to maturity at position highly dangerous throughout its develop- and after, he endeavoured to arrest its growth by rful galvanic currents. This was repeated without . It was then determined to pass a trocar into the , which was done per vaginam readily without any ing. The fœtal movements ceased next day ; but vomit-artly from the chloroform given, continued very violent till about the fifth day, when, sudden collapse supervening, the patient died on the sixth day after the operation.

The post-mortem examination showed that hæmorrhage was the immediate cause of death owing to slight separation of the upper part of placental attachment to the exterior of the uterus, but none whatever occurred at the seat of puncture. The examination also showed a curious fact—namely, that the cyst in which the fœtus originally was formed had ruptured, and that the ovum entire had escaped into the recto-vaginal pouch, and continued to live and grow, the ovular membranes filling entirely the pouch, the placenta being attached to the back of the uterus. On opening the original cyst from above, the ovular membranes were seen through the rupture in the cyst. Dr. Hicks having requested the assistance of the President in elucidating these points, and in giving a report, the report was then read, confirming the above facts, and endeavouring to explain the mode of occurrence.

A discussion then arose between Dr. Routh, Dr. Graily Hewitt, Dr. Greenhalgh, and Dr. Hicks as to the advisability of attempting the abdominal section in such cases.

Dr. MARION SIMS read a paper on

CHRONIC INVERSION OF THE UTERUS,

reciting two cases of his own. In one of these he attempted manual reduction without success, and as the hæmorrhage from which the patient suffered was so excessive as to threaten a fatal result, he determined to ablate the organ. It was attempted first by ligature ; but as this gave rise to severe symptoms, pain, and depression, it was decided to remove it with the écraseur. Severe bleeding ensued from the broad ligament, which was controlled by ligature, and the line of section united by silver sutures. The patient recovered rapidly. In the other case, reduction was effected under ether by the hand. The uterus was grasped and partially restored. By pressing firmly the right cornu with the thumb of the left hand, and pushing upwards, while the fingers compressing the opposite side tended rather to draw the left cornu down, the uterus jumped, as it were, out of the hand, and was restored to its natural condition. The author then alluded to the successful plan of Dr. Tyler Smith by continuous pressure by air-ball, and to Dr. White of Buffalo, for the plan of lateral pressure on one cornu ; and considered that, with the success which had latterly attended attempts at reduction, one should hesitate a long time before removing the uterus for inversion.

Dr. SIDNEY TURNER remarked that the reduction of inversion just mentioned reminded him of the mode of reduction of hernia by the taxis ; and suggested continuous grasping of the organ to empty it of its blood as much as possible, so as to lessen its bulk before attempting its reduction.

Dr. HALL, of Brighton, concurred in the view of the last speaker ; and further suggested that bags of ice might be passed into the vagina to diminish the bulk, instancing the advantage of cold in treatment of paraphymosis.

Dr. BARNES mentioned that Dr. M'Clintock had fully explained the analogy of reduction of inversion of uterus and hernia. He thought that the mode of action by the elastic ball of Dr. T. Smith was by wearing out the muscular resistance of the uterus.

Dr. M. SIMS then replied to the various speakers.

Mr. F. LAWTON related a case of Vascular Tumour of the Funis in a new-born infant, with its microscopical appearances by Dr. Hicks.

MEDICAL SOCIETY OF LONDON.

MONDAY, OCT. 16TH, 1865.

MR. I. B. BROWN, President.

Mr. TEEVAN exhibited

A CALVARIA,

showing a fissured fracture of the *external table only*, produced by a bullet striking the *inside* of the skull. The skull-cap was taken from a Swiss who shot himself a few weeks ago, and died in one of the London hospitals. The

bullet entered the right parietal bone, traversed the brain and its membranes, struck the inner face of the left parietal bone, and remained imprisoned in the cranium. There was no fissure or fracture at the spot on the inner surface of the left parietal bone where the bullet struck, but at the corresponding spot in the outside of the bone there was a starred, fissured fracture of the external table only. Mr. Teevan remarked that this variety of fracture had never been described, and that he brought forward this specimen to corroborate his own experiments on this subject, and in support of a statement which he had made to the Society on a former occasion—that, whether the inside or the outside of the skull be struck, fracture of the distal table only, without injury to the proximal one, can be produced in either case, and that such fractnre occurs in obedience to a well-known physical law—that fracture commences in the line of extension, which is the distal side, and not in that of compression.

Mr. BAKER BROWN exhibied

A LARGE OVARIAN TUMOUR.

The actual cautery had been successfully applied to the pedicle. He stated that he had had thirteen successes out of fifteen cases.

Dr. MURCHISON read a paper

ON HYDATIDS OF THE LIVER, THEIR DANGERS, THEIR DIAGNOSIS, AND THEIR TREATMENT.

The paper was elaborate and exhaustive. It commenced with a report of twenty cases, including all that had been the subject of post-mortem examination at the Middlesex Hospital during the last twenty years, and others that had occurred in the author's own practice. In the course of the paper also, reference was made to all the cases recorded in the Pathological 'Transactions,' and others in the Medical journals. Dr. Murchison pointed out that, owing to the sudden termination of fatal cases of hydatid disease, hospital records hardly gave a fair view of the ratio of deaths from this cause. Although there could be no doubt that an hydatid cyst might become arrested in its growth, shrivel up, and undergo what is called a spontaneous cure, this result rarely happened when the tumour was large enough to be diagnosed during life. In the large majority of cases it went on increasing, and ultimately burst, and when this happened death was the usual result. Attention was directed to the remarkably latent character of hydatid tumours of the liver: in most cases they gave rise to no uneasiness until they had attained such a size as to compress adjoining organs, or until they were on the point of bursting, and peritoneal inflammation was excited on their surface. The directions in which an hydatid tumour of the liver might burst were various. 1. Into the cavity of the chest. 2. Into the peritoneum. 3. Through the abdominal parietes, or lower intercostal spaces. 3. Into the stomach or intestine. 5. Into the bile duct. 6. Into the vena cava inferior. Independently of rupture, hydatids might destroy life—1st. By compressing important organs and interfering with their functions. 2nd. By suppuration of the cyst, or external to the cyst, and pyæmia. 3rd. By the formation of secondary hydatid tumours in different parts of the body. It followed that the risks to which a person with a large hydatid tumour of the liver was liable were many, and the chances of his escaping them were few. Although the tumour might remain stationary for years, an accident might at any moment cause death. Turning to treatment, little benefit could be expected from medicines. Chloride of sodium and iodide of potassium, the two most vaunted remedies, were of no use. It was difficult to conceive how chloride of sodium could destroy an hydatid, seeing that hydatid fluid always contained such a large amount of this salt, which, indeed, appeared to be essential to the life of the parasite. With regard to iodide of potassium, there was not only no proof that it could cause absorption of an hydatid, but there was positive evidence that the drug never reached the hydatid. Not a trace of iodine could be discovered in the hydatid fluid of a patient of Dr. Murchison's, who had taken fifteen grains of iodide of potassium daily for several weeks before. Puncture of the cyst was of much greater promise, and had been attended with great success. The dangers were peritonitis and suppuration of the cyst, but by the employment of a fine trocar these dangers might in a great measure be avoided. The error of using a large trocar, or of making an incision with a scalpel, lay at the root of most of the accidents that had occurred. The evacuation of the fluid through a fine canula sufficed to destroy the life of the hydatid. Of twenty cases of hydatid tumour of the liver tapped as described, and collected by the author, all but three had recovered; and of the three fatal cases, death in one was due to secondary tumours, in a second to a miscarriage, and in the third case the cyst had suppurated and the patient was moribund at the time of the operation. In all cases, therefore, where an hydatid tumour of the liver was large enough to be diagnosed during life, and was increasing in size, the operation of puncture and evacuation of the cyst in the manner described was advisable. But before resorting to puncture, it was of course necessary to be certain of the nature of the tumour. The diseases most liable to be mistaken for hydatid tumours of the liver were, abscess of the liver, a distended gall-bladder, extensive effusion into the right pleura, an aneurism of the aorta or of the hepatic artery, and cancer of the liver. The points of diagnosis from these lesions were carefully considered, but the author believed that what was called "hydatid vibration" was a sign of little importance in diagnosis. In a doubtful case there could be no objection to making an exploratory puncture of the tumour. If the tumour was hydatid the fluid drawn off would at once reveal its nature, even if it contained no echinococci. Hydatid fluid was clear and colourless as water; it had a specific gravity of 1009 or 1010; and it contained not a trace of albumen, but a large quantity of chloride of sodium: these characters applied to no other fluid in the human body, whether healthy or morbid. If the tumour turned out to be cancer, or even aneurism, there was ample evidence that no harm would result from a minute puncture. The paper concluded with the details of a case under the author's care, where paracentesis had been performed with complete success. The patient at the end of a year was in perfect health.

In the discussion which followed, Dr. GIBB mentioned examples of hydatid disease in the young, and a case in which hydatids between the rectum and bladder had been diagnosed and cured,

Dr. ALTHAUS referred to the saline treatment with favour, and as deserving of trial first.

Dr. COBBOLD declared that treatment useless, and referred at length to the great importance of the subject, bearing testimony to the accuracy of Dr. Murchison's results and observations.

Mr. BROWN suggested that, after puncture of hydatids of the liver, a firm, many-tailed bandage should be applied to secure rest and apposition, and prevent effusion into the peritoneal cavity.

LEGAL INTELLIGENCE.

SERIOUS CHARGE AGAINST DR. ROBERT HUNTER.

At Marylebone Police Court, on Monday week, Robert Hunter, of 14 Seymour street, was charged with feloniously assaulting Mrs. Annie Meyrick, on the 14th ult. It was stated that Mrs. Meyrick was suffering from consumption and unable to attend. The magistrate and the parties therefore proceeded to her residence, at 53 Baker street, where Mrs. Meyrick was in bed supported by pillows. She appeared to be about twenty-eight years of age. She said she suffered from consumption, and in September last placed herself under defendant's care. She visited him at Seymour-street several times. She added: I went into the room, and he desired me to sit and inhale something. After I had been doing this some time he said he would examine the pain in my side from which I was suffering. [The prosecutrix here described the outrage alleged to have been committed.] I was not unconscious at all, but I felt stupid, with a paralysing sort of feeling which I cannot describe. I told him

would not enter the house again, and that he was a brute. rushed from the house as quickly as I could.—Cross-examined: She did not see the solicitor for the prosecution ll Saturday last. When she went to Hunter's last there ere many patients waiting to see him. She went up to s room, the others remaining below. A servant man let r in and let her out. On coming out she gave him a illing, because he had always been civil, and because it is the last time she would go there. She did not say ything to him about what had happened. She told her other the same day, and her mother sent next day for Dr. ills, whom witness had seen at Hunter's house. On onday last, witness first told her husband what had ppened, but not the whole of it. Witness and another ctor named Melville came to her three times. They did t say that her term with Hunter had expired, and that she st pay a further fee. Witness was married four years ago at house in Conduit street, Regent street. She had kept a pri- e lodging-house for gentlemen and ladies. On the day the assault Hunter fastened the room door after she nt in. He always used to fasten it. Before she left that Hunter said he would have a blister made up for her. e left and went to Oxford street, and returned, but as blister was not ready she did not wait. When she left nter's place, she went to a friend's at the corner of ebec street.—Mr. Herring (for the prisoner): What is ir friend's name?—Mr. Butler (for the prosecution): n't answer that question.—Mr. Mansfield ruled that she s not bound to answer it.—Witness (further cross-exaned) said her husband called on Dr. Hunter to make a sh arrangement as to his fees, his month being up. On ling this to witness she said she would not go again Dr. Hunter, and she partly told him of what had hapned. She was aware they were to have gone this day Clerkenwell Sessions to answer Dr. Hunter's charge of ault.—Mr. Herring addressed the magistrate for the ence, and pointed out the improbability of the com inant's charge.—Mrs. Meyrick (raising herself up): ll the magistrate allow Hunter to stand up before me, then see if he will say he has not insulted me as I e said?—She was informed that this could not be owed.—After some further discussion, Mr. Mansfield ourned the case, accepting the prisoner's own bail in 00*l.* and two sureties in 2,000*l.* each for his reapearance.

On Saturday last the hearing of the case was resumed, n Mr. Sleigh, for the defendant, said he found from depositions that there was not a tittle of evidence oborative of the statement of Mrs. Meyrick. He also rved that Mrs. Meyrick had stated in her evidence that e were three persons who could depose to the facts on h the prisoner was charged, but not one of those ons had been called. The evidence having been sworn, Sleigh urged that he should be allowed to cross-mine Mrs. Meyrick. Dr. Hunter was charged with an ce for which, if guilty, he ought to be most severely shed, but, if he were innocent, it was terrible to him. r. Mansfield said that if Mrs. Meyrick could be pro- examined he should not interpose any objection, and he parties concerned then again proceeded to Mrs. ick's bedroom, where Mr. Butler said: When we were last Monday you refused to give the name of your d upon whom you called, and as your silence might be nstrued, I again ask, do you still refuse to give it?—Meyrick: Her name is Mrs. Sharland, living at 237 d street.—Cross-examined by Mr. Sleigh: The next fter this occurred was a Sunday, and on the Monday nother went for Dr. Wills—not for Dr. Wills exactly, or a doctor. I sent to Dr. Hunter to send a doctor to On that Monday I saw another doctor, and that was Wills. He came here to see me. That was the first I saw Dr. Wills. I went to Dr. Hunter's on Saturday, 4th of October. It was about 11 o'clock, and I had it a long time to see him. When I got home it was een 2 and 3 in the afternoon. I think it was more two hours before I saw him. It must have been conably past 1 when I saw him, because it only took a minutes to go home in a cab. I was only five or ten minutes at my friend's. I went straight to my friend's from Dr. Hunter's. I went straight to Mrs. Sharland's, and stayed with her about ten minutes, and went back to the doctor's for a bottle of medicine. The person I asked for the bottle of medicine was the one I usually saw, and who opened the door to me. He was the same man that opened the door to me and let me out on my first visit. It was on the second occasion of my calling that I gave the man the shilling, and it was on the second occasion I got the medicine from him. I felt very ill then, and I hailed a cab about two doors from Dr. Hunter's house, and went straight home. I called on no one else, only Mrs. Sharland. I saw no Medical man on Sunday. I am quite sure it was on a Monday my mother went for a doctor. My mother went on Sunday afternoon, but no one being there she went again on the Monday. The lady I have mentioned is the widow lady I referred to before.—Re-examined by Mr. Butler: I knew it was Dr. Hunter's practise not to come out himself. Therefore I knew when I sent my mother for a doctor on the Monday there was no chance of his coming out.

All parties then returned to the court, when Mr. Sleigh said it was now his part to address the magistrate, and to ask him whether he was going to send the prisoner for trial. He did not hesitate to say that there was no evidence to support the charge. It had been said that the defendant was not qualified to practise in this country as a medical man. He had not qualified in any university in this country, it was true, but he had elsewhere, and stood in precisely the same position here that one of our Medical Profession would have done in America. Let them dismiss any prejudice against him on this ground, and keep strictly to the matter at issue. He had been astounded at the manner in which the prosecution had been conducted by Mr. Butler. He was astounded at his refusal to call witnesses. He then entered very fully into the allegations of the prosecutrix, and endeavoured to show the great improbability of her statements. He concluded by saying he would prove that on the 14th, when the occurrence was said to have taken place, the prosecutrix did not see the prisoner at all.

Witnesses were then called on the part of the prisoner, and on the close of the case Mr. Mansfield said this is a very important case, and to none more so than the prisoner before me, and it is desirable that his defence be before the public as soon as possible. He has been most ably defended, but it seems to me there is such a conflict of evidence that it is essential the case should go to a higher tribunal. His worship gave the prisoner the usual caution as to what he might have to say being reduced to writing.

Prisoner.—I say the charge is deliberately false in every particular.

The prisoner was then fully committed for trial at the next Central Criminal Court sessions. He was admitted to bail, himself in 4,000*l.* and two sureties in 2,000*l.* each.

IMPOSTORS AND DUPES.

The modern system of easy advertising and the facilities of the penny post have many advantages, but they have also their attendant evils of no little weight. One of these evils is nothing less than a curse upon English society. Occasional exposures in the law courts and the newspapers have long made us familiar with the advertising practices of a certain class of Medical impostors, and with the misery they inflict upon their unhappy dupes. Persons who turn over the pages of the cheap newspapers in search of the curiosities of advertising will have noticed the frequent recurrence of a whole column, purporting to give a consecutive series of extracts from a Medical work on consumption by a person signing himself Robert Hunter, M.D. If they have taken the trouble to read its uninviting paragraphs they will have found that they are a long rigmarole of semi-scientific declamation, professing to expound to the non-professional invalid the causes and symptoms of disease of the lungs, and to prove that nobody knows how to cure it except this same Dr. Hunter, whose method is one of inhalation. On the face of all this there is nothing more than the puffery of the dealers in the various pills, potions, ointments,

and liniments, who rejoice in the possession of testimonials from innumerable correspondents who bless the day that they first made the acquaintance of the pill, potion, ointment, or liniment in question, and who are all alike in an unfortunate ignorance of English grammar. That any first-class physician would thus advertise for patients is, of course, out of the question. But although these advertisements are free from the mysterious hints and suggestions and the scarcely veiled offensive phraseology of the basest class of Medical puffs, one is led to suspect the existence of very serious malpractices by observing the length and the frequency of these recommendations of Dr. Hunter and his inhalations. When a man finds it worth his while to insert a very costly advertisement in several papers, and to go on with it from day to day or week to week, it is clear that his patients must be dupes of a very different class from the simple people who buy pills by the gross and potions by the gallon. There is no need of the revelations of a police-court to show that the inhaling process means a process for working upon the fears of the ignorant, and for obtaining enormous fees. Men like these advertisers know well that there is one class of society which is specially open to their allurements. Ladies and gentlemen, and the more wealthy and comfortable class of tradesmen have, as a rule, their regular family doctors. They dislike doctors' bills as much as any other bills; and it is sometimes hard enough to pay them. But still, until we go farther down in the social scale every man has his own doctor. Then comes an immensely numerous class, whose real education is not much above that of the actual poor, and whose experience of life is confined to a narrow range. These are the men and women who are the destined victims of the advertising doctors. They read about mucous membranes, and carbonaceous blood, and tubercular deposits, and are impressed with the genius of the gentleman who can thus easily make them familiar with the profoundest secrets of science. If they have anything really the matter with them, their disagreeable sensations are at once intensified; if they have nothing more than a cold in the head or a tightness in the chest, produced by over-indulgence at supper, Dr. Hunter's catalogue of terrific symptoms suggests a mysterious signification to their pains. And when, at last, the advertisement recommends them to "put their worldly affairs in order and withdraw their minds from all earthly ties," for they have only "a few short months of life" before them—*i.e.*, unless they consult Dr. Hunter—what else remains but to go the next morning to see the pious, learned, and benevolent physician? Once in the toils of the physician's "consulting room" the rest is clear. A man must be a sorry practitioner indeed if he cannot work upon the terrors of a foolish woman, especially if she is really ill, and so keep up the game of questioning, and examining, and physicking, until the poor victim's purse will bleed no more. If, as is often the case, the patient is a man whose confessed "indiscretions" furnish a pretence for all sorts of horrible suggestions as to his ruined constitution, the process is equally easy, and the profits to be expected even more exorbitant.

It should be an indictable offence for any man to call himself a physician, surgeon, or apothecary, unless empowered to practise by the colleges or societies recognised by the law of the land. The assumption of all foreign Medical degrees should be absolutely forbidden under the same penalties, whether claimed by English subjects or by foreigners. English subjects are forbidden to assume any foreign title of rank without the permission of the Crown. But what would be the evils of permitting some foolish gentleman to call himself count or baron compared with the mischief done by persons who claim to be respected as qualified physicians on the strength of some diploma obtained in Canada or New York? In a late number of the 'Daily Telegraph' we find three advertisements, side by side, all professing to come from qualified practitioners, and varying only in the greater or less freedom with which they disclose their real purport. One man calls himself "Dr. Hammond, of the Lock Hospital, F.S.A.;" another, "Dr. Bray;" and a third, "Mr. Abercrombie, Member of the Royal College of Surgeons." We can only wonder how much of all that these persons claim is true in any way whatever, and must also ask whether the College of Surgeons permits its "members" to advertise themselves in the newspapers.—'Pall Mall Gazette.'

[Dr. Robert Hunter's advertisements appeared in the 'Times' as well as in the "cheap" newspapers.—ED. MED. CIRCULAR.]

PARISIAN MEDICAL NEWS.

STATISTICAL RETURNS OF M. VELPEAU'S HOSPITAL PRACTICE.

Although we can assign no reason for the fact, erysipelas is now more frequent and more formidable than formerly. During a hospital experience extending over thirty years, M. Velpeau has met with two hundred instances of the disease only, whereas in the past year, he has counted in his wards no fewer than thirty-five cases, twenty-one of which were the consequence of traumatism and proved eventually fatal. This increase is especially remarkable, because at La Charité as well as in other hospitals periods of ten and and fifteen months sometimes elapse without the occurrence of a single instance of the disease.

A host of remedial agents have been recommended for the cure of erysipelas, and every year fresh methods of treatment are brought forward, which according to their authors must infallibly succeed in checking the progress of the scourge. M. Velpeau has considered himself bound to give a trial to all these various suggestions, but acknowledges that, hitherto, he has been unable to do more than to mitigate and perhaps in some degree to direct the course of the disease for which, however, he has in no instance discovered any immediately effective remedy. The Professor has often stated, and once more repeats, that erysipelas never lasts more than four days in the same spot, but as it progressively invades the adjacent parts, its duration which averages eight or ten days, may extend beyond six weeks. Despite all assertions to the contrary, M. Velpeau contends that erysipelas never induces suppuration. When the disease coincides with the formation of pus, the fact is due to the coincidence of secondary phlegmon or of cellular inflammation, which sometimes also is the cause of the development of erysipelas.

The manner in which erysipelas destroys life has never yet been correctly understood, but it appears highly probable that the fatal issue is the result not of simple inflammatory action, but of a morbid state of the blood generated in the system, and exercising its poisonous influence on the structures most necessary to the continuance of vital operations.

Burns somewhat resemble erysipelas with respect to the general inefficacy of local appliances, on the curative power of which the surgeon should express a very guarded opinion. In the first and second degrees (rubefaction and vesication), burns may be relieved by a large number of remedial agents. Carron oil, a liniment composed of equal parts of oil and lime-water, is the application in which the Professor reposes the greatest confidence, especially when the face and hands are concerned. Talc has been strongly recommended, but M. Velpeau has not been entirely satisfied with its effects; this substance soils the dress and bed-clothes, and is not possessed of any virtues superior to those enjoyed by other absorbent powders such as bismuth or common flour. A convenient method of treatment consists in covering the affected parts with strips of adhesive plaster. When a deep burn has given rise to mortification, the usual dressing of wounds should be resorted to, and it is especially in this instance that the inefficacy of the many nostrums advised for the cure of burns is most obviously apparent.

In contusion, as well as in burns, it is useful for practical purposes to discriminate between the various degrees of injury inflicted.

Eighty-four cases of bruises of various degrees of severity were this year admitted into the wards. In many of the patients the skin was merely abraded, whereas in others

travasation of blood was also produced. Effused blood is adily taken up by the absorbents, and various procedures e applicable to the cure of collections of that liquid. rushing disperses the effused blood into the neighbouring ssues and is the simplest of all remedial measures, espe-ally when the deposit rests on a solid surface such as that the bones of the skull, of the tibia, &c. But if the mour glides from the pressure of the thumbs of the erator and thus eludes his efforts, discutients, and, if cessary, the knife must be resorted to. The trochar and e iodine injection are appropriate when a change in the mposition of the extravasated blood has taken place, ring rise to hydrocele or to hematocele ; but if coagulation s occurred and a solid mass is formed enclosed in a cyst, e tumour should be extirpated. Upwards of 1,560 cases e adduced by the Professor in support of these views.

An interesting circumstance connected with the history of ntusions—viz., the jaundiced hue of the entire integument sequent on extensive injuries of this description, hough no hepatic complication may exist, has hitherto ceived no satisfactory explanation. The discoloration es not extend to the sclerotic, and is not of any serious portance, spontaneously disappearing in the course of e or six days.

M. Velpeau's returns for the last year include 209 in-nces of disease of the breast and organs of generation—., eighty-three in men, and 126 in women. In addition, hteen accouchements occurred in the wards. Amongst e mammary affections, we note twenty-two abscesses, e case of uncomplicated hypertrophy, three of chronic flammation, and six glandular tumours, besides thirteen ncers, one of which was observed in a male subject. even of these malignant growths were removed by exci-n, with entire success in six patients. A cure was ected (by amputation) in every one of the six instances glandular enlargement.

Sixty-three cases of disease of the organs of generation re observed in women—viz., abscess or cyst of the labia, a ; uterine deviation, five ; pelvic inflammation, nine ; arian disease, seven ; fibrous tumours, eight ; cancer, arteen ; and fistula, three.

In almost every instance, abscess of the labia pudendi as traced to sexual over indulgence, but M. Velpeau is t altogether satisfied that the affection invariably origi-ates in inflammation of the glands of Bartholine.

The Professor's opinion of the import of uterine devia-ns has undergone no change. He still contends that is class of diseases is not of so alarming and serious a aracter as authors have alleged, but acknowledges that en the displacement exists in a very marked degree it y possibly interfere with menstruation and conception. franc conceived that these deviations were the result of onic uterine inflammation, and that the treatment uld be directed with a view to the removal of the latter. theory has, however, of late been sharply criticised, seems to have been finally disposed of in the debates ch have arisen on the subject at the Academy of icine, in which both deviation and chronic inflamma-were set aside. M. Velpeau objects to all mechanical rference with uterine displacements. When they occa a much inconvenience, he recommends the use of a ogastric belt which giving the required support to the ominal viscera relieves the womb from undue pressure, permanently affords the alleviation which the patients in in a temporary manner by the application of the ds.

Our readers are acquainted with the measures recom-nded by Professor Velpeau in metro peritonitis ; they sist in large blisters, mercurial ointment, aperients, hs, and occasionally local depletion.

Blisters and resolutive ointments are also prescribed at Charité for fibrous tumours, in which these remedies metimes succeed in effecting a diminution, and exercise a durable influence on the tendency to hæmorrhage.

We will barely allude to uterine cancer, which occasions little pain, and may for a long time escape detection.

In the male subject, M. Velpeau's statistics for the year sent us with a total of thirty-five cases of orchitis, and twenty-two of hydrocele. The entire number registered in thirty years, being orchitis 600, and hydrocele 400. The average duration of orchitis in which the tunica vaginalis should, according to M. Velpeau, always be punctured with a lancet, varies from two to three weeks.

Phymosis and paraphymosis now claim our attention. In the former, M. Velpeau performs an incision near the frænum. In the latter, reduction is effected by a simple but effective procedure, consisting in forcing back the glans with the fingers of one hand, while the penis, protected by a dry compress, is supported by the other.

Diseases of the anus, to which we shall briefly allude, were almost invariably observed in the male. M. Velpeau remarks that the term fissure has too frequently been applied to simple ulceration, a circumstance which accounts for the success alleged to have been obtained by numerous local appliances. The true fissure, with sharp edges, extending longitudinally ten or fifteen lines in one of the folds of the orifice can seldom be cured without recourse to the knife.

M. Velpeau has not enjoyed sufficient leisure to supply us with a return of his ophthalmic practice, and concludes with remarks on the mortality after operations.

One hundred and twenty operations of the more important class were performed in the course of the year, and their sequelæ have shown that no dressing affords any absolute immunity from erysipelas or puriform infection. Alcohol has been resorted to for this twofold purpose, but without avail, and the Professor is satisfied that the use of this or other simulant substances is not more perilous than that of anodyne dressings, and is a cleaner and more convenient appliance.

With regard to the mortality, out of twenty-eight operations for cancer, eleven had a fatal issue, a result which cannot be viewed as unfavourable, if it be remembered that the disease for which excision was resorted to is of a hopeless character.

Fifteen operations were followed by erysipelas which terminated fatally.

Ten patients died of puriform infection.

In four cases of extensive burns, in four of metro-peritonitis or pelvic suppuration, and in five of compound fracture, death also resulted.

It is needless again to revert to these morbid conditions and injuries, but we must remark that M. Velpeau reposes no confidence in the various remedies recommended for the cure of pyæmia. Temporary feverishness, ushered in by a shivering fit, a fews days after an operation, has often been mistaken for this formidable disease, and on the subsidence of these symptoms the surgeon flatters himself he has succeeded in checking the progress of puriform infection. It may not, however, be absolutely impossible that the system may in mild cases spontaneously eliminate the poison which has given rise to the morbid manifestations, as it has a tendency to throw off all septic substances in general, a view which casts, it is true, but little light on the subject, but should encourage further inquiry into the means best calculated to assist the efforts of Nature.

JUST LUCAS-CHAMPIONNIERE.

ANTAGONISTIC EFFECTS OF OPIUM AND BELLADONNA.

We find, in the 'Gazette Hebdomadaire' of August the 11th, a memoir from the pen of Dr. Camas, of Saint-Quentin, in which the author, from experiments instituted on animals on the reciprocal effects of opium and belladonna, deduced the following conclusion :—

"The alleged antagonistic action of opium and belladonna is not observable in rabbits or sparrows, and I am of opinion that it does not exist in the human subject." M. G. Lubelski, physician of the Hospital for Infancy at Warsaw, cannot agree in this view, and at the very date of the publication of the memoir adverted to he witnessed a case, the particulars of which he has since forwarded to the same journal.

"Sister M. V. F. Newska, a nun of the Order of the Holy Sacrament at Warsaw, had for several years suffered from severe hysterical attacks, for which she fruitlessly consulted six or seven Medical Practitioners, and had absolutely ex-

hausted the resources of the materia medica, from the mildest antispasmodics to the actual cautery ; so refractory had she become to the action of remedial agents, that twenty-five grains of acetate of morphia were required to conquer for a few moments the morbid tendency, and induce short intervals of repose.

"On the 16th of August, the symptoms having recurred with unusual severity, Dr. Natanson, one of our most eminent colleagues, the president of the local Medical society, was summoned to her assistance, and having noted the peculiar hysterical scream, doubtless occasioned by simultaneous spasmodic action of the larynx and diaphragm, prescribed one grain of valerianate of atropia, divided into sixty pills, one to be taken night and morning.

"Scarcely had the third pill been exhibited, when symptoms of poisoning became manifest, and increased hourly with such violence, that I was sent for in haste on the night of the 18th-19th of August to visit the patient, whom I had long been acquainted with, although I had never attended her professionally. I found her supported by the nurse and the Lady Superioress, and she had received the last rites of the church. The eyes were bright, the throat dry, and the excretions checked in spite of repeated enemas. She was, however, gradually recovering her speech and the power of deglutition, which for some hours had been paralysed.

"I prescribed at once ten drops of Sydenham's laudanum, and repeated the dose five or six times at intervals of half an hour, and administered in addition a large quantity of milk and pure coffee, which was swallowed with much difficulty. A hot foot-bath, containing wood-ashes and mustard, mustard poultices applied to the epigastric region and to the legs, and two enemas with castor oil, completed the cure, and at 5 a.m. the patient fell asleep. Yesterday evening, at 6 p.m., I found her much better, and complaining only of epigastric tenderness. She had already taken fifteen grains of morphia, and intended to take ten more. During the proceeding night, I had exhibited sixty or seventy drops of laudanum, an amount equivalent to four and a half grains of opium."

As the author remarks, this case presents several points of interest.

In the first place, the immense quantities of morphia taken by the subject show how easily the system becomes reconciled to the habitual use of poisons.

In the second, the poisonous effects produced by so very small a dose of valerianate of atropia, exhibited in the course of thirty-six hours, demonstrate the expediency of M. Schroder Van der Kolk's and M. Kroon's precept of prescribing very minute doses of this substance, especially at first. These gentlemen begin by the one hundred and twentieth part of a grain, and increase the amount very gradually, adopting at the same time all the precautions recommended by MM. Michéa and Maresch, of Vienna.

The case further justifies Schroder Van der Kolk in his rejection of the valerianate of atropia in the treatment of genuine hysterical affections, a view entirely shared in by M. Lubelski, who has instituted experiments on the subject, and by his colleague at the Hospital for Infancy, Dr. Frydych, who is well known for his contributions to mental pathology.

We may further observe, that even in the case of a person accustomed to the daily cousumption of an enormous dose of morphia, opium preserves its power as an antidote to atropia, and that its action is extremely prompt, a result which, taken in conjunction with other facts, invalidates the opinion brought forward by Dr. Camas, of Saint-Quentin.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—An election of two annuitants, each to receive 30*l* per annum from the Benevolent Fund of this Society, took place on Friday, the 27th ult., when David Peart and Charlotte Peart Goldfinch were declared to be the successful candidates.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 7th inst., and when eligible will be admitted to the pass examination :—Frederick Henry Blenkinsop, St. George's Hospital ; Walter Henry Drew, University College: Benjamin Duke, Guy's Hospital ; Thomas Harvey, St. Thomas's Hospital ; Frederic William Hodder, Toronto; Jeremiah MacCarthy, Dublin ; Barney Constance MacEgan, Galway ; Henry Murray Steele, University College ; Richard Wilson, St. George's Hospital.

At this meeting, Mr. Richard Quain, F.R.S., the recently elected member of the Court of Examiners took his seat.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on the 2nd inst :—Samuel James Hulme, Infirmary, Manchester ; John Hurd Wood, Notting Hill ; John Loane, Dock street, E. ; Thomas Francis Raven, St. Bartholomew's Hospital.

The following gentleman also on the same day passed his first examination :—Septimus Evans, St. Bartholomew's Hospital.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—An ordinary general meeting of this Society was held on the 25th ult., when were elected B. G. Babington, M.D., and Charles Hawkins, Esq., Vice-Presidents of the Society ; also John Scott, Esq., of Harley street, a director, to fill up vacancies in the list of officers. The Treasurer's accounts for the first six months of the year were also read, from which it appeared that eighty persons, widows and orphans of deceased members of the Society, had received relief, ordinary and extraordinary, to the amount of 1,177*l*. 10s. during that period.

UNIVERSITY COLLEGE, LONDON.—The Council held their first session for the academic year 1865—66 on the 4th instant. The Longridge Prize of 40*l*. for general proficiency in Medicine and Surgery, was awarded, on the recommendation of the Faculty of Medicine, to Mr. Bryan Holme Allen, of London. The Filliter Exhibition of 30*l*. for the encouragement of proficiency in Pathological Anatomy, was on the report of the examiners—Prof. Sharpey, M.D., Prof. Erichsen, and Prof. Wilson Fox, M.D.,—conferred on Mr. John Williams, of Blaenllynant.

THE ROYAL ALBERT INFIRMARY AT BISHOP'S WALTHAM, the foundation-stone of which was laid by Prince Leopold last year, was opened on the 7th instant by the same youthful Prince, accompanied by his sisters, the Princesses Helena and Louise. A statue of the late Prince Consort in terra cotta, modelled by Theed after his design of the Coburg statue, was also uncovered on the occasion. The building was designed by Mr. Critchlow of Southampton, and has accommodation for twenty beds.

THE FORCE OF HABIT. Dr. Gairdner, in a memorandum on Dr. Anderson's report of the state of the water in the twelve wells in Glasgow, observes that the produce of the two worst wells is highly relished by the drinkers. "Nos. 9 and 10 must be condemned without reservation. In the case of Bridgeton Well, indeed, it is perfectly obvious that the water is within the range of soakage of a great quantity of stable manure, as well as of a privy in the immediate neighbourhood. Yet, although these facts are quite notorious, or at all events can be ascertained with much difficulty, they do not hinder the water of this well from being extremely popular, and I am told that an attempt to remove the well some years ago was strongly resisted. Probably the peculiar flavouring comes by long habit, to be rather relished than otherwise; and I do not doubt that some of the drinkers consider this pump as superior to Loch Katrine."

A DISEASE AMONG THE CATS.—A disease has been prevalent in Forres for several weeks among the feline species, which has cut them off in every direction. The animals appear to be disinclined for food for a day or two —then they have running of water at the mouth and nose, dull bleared eyes, and great prostration of strength. They

about the hearth or in by-corners, and do not touch of any kind for days They generally die on the or ninth day.—'Forres Gazette.'

FOUNDLING HOSPITAL.—The following particulars rence to the early history of the Foundling Hospital ldford street, will indicate the results that might be ed if such an institution were open to all comers. 1741 to 1756 the average number of children received per annum, or 1,384 in all. The governors aspired conduct of a much wider charity than that they had o administered, and they applied to Parliament for id. Solomon says there is "nothing new under the nd the "social evil," and infanticide, and projects for are, would seem to be amongst the immutabilities. ient readily decreed that all children offered at the l should be received; that state aid for the main- of the hospital was indispensable, and would be that branch establishments should be set up in "all s, ridings or divisions of the kingdom, for the reception ted and exposed infants." As was most meet Parlia- ve the governors a pecuniary guarantee, in carrying vast scheme of charity. The effect of these resolu- as disastrous. The Legislature created a Franken- nich they could not control, and which they had o kill. On the first day for general reception, after lutions took effect, 117 children were deposited, in cession, in the basket hung outside of the gates of the The workhouses were emptied of infant poor; brutal bbed their wives of newly-born infants, and conveyed he Government sanctuary; travelling tinkers, har- thout feelings, and ruffians of both sexes, engaged the new trade of conveying infants from distant the country to the London Foundling Hospital—a centage of the infants, as may be supposed, perish- he way. It was publicly stated in the House of s that one man in charge of five infants, whom he o convey to the Foundling Hospital, got drunk, leep on a common, and found three of his charge n he awoke. Of eight infants brought to town in a even at the end of the journey needed sepulture, ng. The price for conveying children from York- panniers was eight guineas a trip, until competition down the rate. In many instances, the heartless who engaged in this nefarious trade stripped their le victims, and left them naked in the hospital Some years since an aged banker in the north of who had been brought up in the Foundling, made s to his origin—all the information the books as that he had been "left in the basket naked." system of indiscriminate admission the hospital charnel-house rather than a nursery. The due enormous number of infants thrown upon the s beyond the powers of any institution. In the ,296 infants were admitted; in the second, 4,085; l, 4,229; and during less than ten months of the ; 3,324—that is, in less than four years, 14,934 e cast upon the care of the public. Of this y 4,400 survived to be apprenticed! and the ortality thus indicated cannot be wondered at if ture of infant life is kept in view, and the toil volved in infant training. A nurse has a very full h two infants, but if *mothers*—the natural, the heapest nurses—are to be released wholesale ischarge of their natural duties, the result in ality, and the money cost to the community, o be very serious. The House of Commons pt the cautionary suggestion of Captain Coram nd proper care" in the conduct of the charity, hat they had established a market for vice, l their steps, and resolved, "That the indiscrimi- on of all children under a certain age in the been attended with many evil consequences, e discontinued."

ALFRED MONCKTON, ESQ., M.R.C.S., L.S.A. great regret—a feeling which will be shared by er of the members of King's College—that we e death of the above most estimable mem- ber of our Profession. He died at Brenchley, Kent, of typhus fever, contracted in the discharge of his Professional duties, at the early age of twenty-six years, and at his funeral which took place on November 6, upwards of 300 of his neighbours followed to the church, which was crowded to excess. All commercial pursuits were suspended for the day. The deceased was in charge of an extensive prac- tice which had been in his family upwards of two centuries.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting on Monday, November 6, 1865, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair, D. Chauncy Beale, Esq., and Protheroe Smith, M.D., were elected members of the Royal Institution. The special thanks of the meeting were returned for the following ad- dition to "The Donation Fund for the Promotion of Experi- mental Researches:"—Professor Faraday (third donation), 20*l*. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

THE SKULL OF BEN JONSON.—In the course of a paper read this week by Dr. Kelburne King, President of the Hull Literary and Philosophical Society, before the mem- bers of that society, on "The Recent Visit of the British Association to Birmingham," the Doctor, in speaking of a visit which he and Dr. Richardson, of London, had made to Shakespeare's birthplace, at Stratford-on-Avon, narrated the following curious incident:—He said that a blind gentleman, who thought that no one but the guide was pre- sent, mentioned that a friend of his had a relic which would be a valuable addition to the Shakesperean Museum at that place,—the skull of Ben Jonson. This friend had attended the funeral of Dr. ——, at Westminster Abbey, when he perceived that the next grave, that of Ben Jonson, had been opened, and he could see the skeleton of the body in the coffin. He could not resist the opportunity of putting in his hand and extracting the skull, which he placed under his cloak and thus carried it off. From a remark which the blind gentleman dropped, Dr. Richardson thought he could identify the offender, and he asked if the person's initials did not consist of certain letters. The blind gentleman, who was not a little startled at finding that his secret was out, admitted the fact, but prayed that no advantage might be taken of the discovery. This was pro- mised; but, as Dr. Richardson is an ardent admirer of the Avonian bard, he is determined that, without going to extremities, he will bring the necessary pressure to bear on the possessor of the skull, so that it shall be placed in a more worthy repository than the cabinet of an obscure individual.—'Manchester Guardian.'

DEATH.

TUSON.—On the 10th inst., at 6 Devonshire street, Portland place, Edward William Tuson, F.R.S., F.L.S., F.R.C.S.E., in his sixty-fourth year.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, NOV. 15.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, NOV. 16.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, NOV. 17.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, NOV. 18.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

MONDAY, NOV. 20.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metro politan Free Hospital, 2 p.m.

TUESDAY, NOV. 21.—*Operations* at Guy's Hospital, 1½ p.m. Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Essay on the Nature and Treatment of Cholera and Fever. By James Tucker, M.D. Dublin: Falconer.

Rinderpest: its Prevention and Cure; and Glypsum as a Sanitary Agent. By John J. Lundy, F.G.S., &c. Edinburgh: W. P. Nimmo; London: Simpkin, Marshall, and Co.

A Practical Treatise on Urinary and Renal Diseases. By William Roberts, M.D. London: Walton and Maberly.

On some Varieties and Effects of Cancerous Disease of Bone. By William Hickman, M.B. London: Robert Hardwicke.

A Guide to the Treatment of Diseases of the Skin. By Thomas Hunt. London: T. Richards.

Transactions of the Pathological Society of London. Vol. XVI.

Clinical Lectures and Reports. By the Staff of the London Hospital. London: John Churchill and Sons.

Manual of Materia Medica and Therapeutics. By F. J. Farre, M.D., F.L.S., assisted by Robert Bentley, M.R.C.S., and Robert Warrington, F.R.S. London: Longman, Green, and Co.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the Office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause thereof, and have made such arrangements as will prevent the possibility of a repetition of the same. Any gentleman not having received his copy as usual during the last three weeks, will be kind enough to intimate the same to the Publisher.*

THE EPIDEMIOLOGICAL SOCIETY.—The notice has been received.

DR. W. P. BRODRIBB.—The letter has been received, and the notice shall be sent to the proper quarter.

DR. EDWARDS CRISP'S paper "On the Sheep Plague," has been received.

MR. E. DOYLE (Colne, Lancashire).—We believe that the formula is given in our report, published this week, of the last meeting of the Obstetrical Society.

THE OBSTETRICAL SOCIETY OF LONDON.—The report has been received.

MR. ROBERT C. MOON.—The paper alluded to has not yet reached us, but when it arrives and has been put in type, we will send the proof as directed.

DR. R. T.—The weekly examinations at the College of Surgeons have been discontinued for some years, and the candidates are now examined at periodical intervals, notice of which is previously given.

SCRUTATOR.—We are unacquainted with the professional qualifications of the person alluded to, if indeed he possesses any.

MR. C. B.—The letters have been received, and the request shall be attended to.

PALMAM QUI MERUIT, FERAT.—The letter is inserted.

GRIFFIN TESTIMONIAL FUND.

SIR,—The following subscriptions have been further received on behalf of the above fund:—

	£	s.	d.
G. D. Brown, Esq., Ealing . . .	0	10	0
Hy. Boxall, Esq., Horsham . . .	0	5	0
Amount previously announced . .	129	13	0
Received at 'Lancet' Office . . .	9	9	0

Yours obediently,
ROBERT FOWLER, M.D.,
Treasurer and Hon. Sec.

145 Bishopsgate st., Without,
Nov. 8, 1865.

ERRATA.—Page 319, column 1, MEDICAL CIRCULAR, Nov. 1st, line 29 from top, for "warm" read "hot;" at the conclusion, for "Batheggie" read "Balbeggie."

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 78 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments forwarded for 6 stamps.

Brass and Zinc Door-Plates.

—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges. Chemists' Shops fitted up with Window-sill Plates in the plain or O.G. Patterns. Lists of Prices post free.

Plates altered and repaired.—Country orders punctually attended to.

36 CHANDOS STREET, CHARING CROSS, W.C.

Treloar's Kamptulicon,

COCOA-NUT MATTING,

AND OTHER DURABLE FLOOR COVERINGS,
67 LUDGATE HILL, LONDON,
Three doors from the Railway Bridge.

William Hawke, Wild Court, Great

WILD ST., DRURY LANE, LONDON W.C., (late Ansell and Hawke), Manufacturer of every description of Shop Fittings, Dealer in Medical Glass, Earthenware, and all kinds of Shop Utensils, Medical Labelling, Writing, and Embossing on Glass.

Drawings, Specifications, and Estimates furnished for Fitting-up Druggists' Shops and Surgeries with every requisite, and for erecting Shop-fronts. Druggists' Stocks and Fixtures valued.

Medical Fixtures and Glass Manufactory,

FACTORY, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Entering in the above Profession, that he has an extensive assortment of SHOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c. of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc

H. Silverlock's Medical Label Warehouse,

Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctor's Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.
YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.
SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.
LABEL CASES for the use of Surgeons, 14s., 18s., and 24s.
LATIN SLIP LABELS for Wholesale Druggists.
Catalogues sent on application.

Geo. Smith and Co.'s Pure Extract of CALVES' FEET for INVALIDS and CULINARY USE, in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Italian Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland street, Regent street Office: 94 Upper Thames street, E.C.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

CHLOROFORM EXPERIENCES.

By Charles Kidd, M.D., M.R.C.S. Eng.,
Associate of the Surgical Society, Ireland, &c., &c.

One is asked occasionally such simple, yet withal, practical estions (by letter or in consultation) as to chloroform—its *dus operandi*, its safety in certain contingencies, the class cases where it is most dangerous, the best form of in-ler, &c., that I am tempted to offer your readers a few perfect notes of some recent cases, which illustrate these rticulars as well as others, as to the manipulative skill netimes called into operation in its exhibition, the preju-es that favour illegitimate practice, and impede the pro-ss of anæsthetics as a scientific study.

The use of chloroform in midwifery in London is extend-widely and wisely, but chiefly on account of the agita-n in favour of quack compounds—"omne ignotum pro gnifico"—which have been largely advertised, and iced favourably by leading journals, a sad but instructive ion, not the first, however, in our own half-Medical litera-e, "*judex damnatur cum nocens absolvitur*," the judicious, et, science man is blamed and injured, while the quack bsolved, quackery spreading on every side, and this is due efly to ourselves.

n ovariotomy, I have administered chloroform in some ty operations, and studied its effects in perhaps twice t number of such patients. The tolerance of the agent these cases is very wonderful. One often sees worse cts after tooth-drawing under chloroform. In something a dozen of these operations, the adhesions were severed a red-hot iron introduced into the belly; no pain was felt, l the result was most excellent; the recoveries unusually d. We cannot estimate the value of chloroform here, by striving to picture such an operation *without* chloro-n, as we had once on a time excision of the knee without roform, laid aside on account of the agony inflicted. us ask, indeed, where would now our galaxy of ovari-nists that we wot of all be, but for the grand discovery Morton, and this most singular tolerance of chloroform ng the operation?

s to manipulation, the obstetrician who exhibits chloro-will require to have all his wits about him, and to enjoy l use of both hands; there is nothing, in fact, to pre-him administering ambidexter-wise the chloroform with eft hand, while the right is engaged in the dubious, but ssary, ceremony of supporting the perineum. In a ur-case of this kind, at Highbury, one night not very long the inmates of the house having gone to bed, I found monthly nurse (the only person out of bed) suddenly stupid, and fall senseless on the floor, just as the head ie child of our patient began to press on the perineum. parturient lady, too, showed signs of weakness. The was suddenly born; yet I never relaxed giving with the and the chloroform. I caught hold of the bell-pull my teeth, threw some water at the nurse, tied the kept my hand over the uterus in the same way, and all ight; but I very much envied some old gentleman reus, was it?) who had a superfluity of hands!

e opinions of even some of our leading men are occa-lly, as to chloroform, crude and saddening. Chloro-, they say, has "come in" since they were students, and dwifery they cannot see their way to its use in a moral as a primæval ordinance had arranged pain as a sary penalty, or blessing, or stimulus (they scarcely which), to the parturient female; but the feminine portion of the public are fast going into the other extreme of these opinions, which are too often crude and erroneous.

In one obstetric case recently much talked of, which was prevented coming before the law courts by a little judicious management, the parturient lady had had chloroform during labour and made a good recovery, but suddenly on the sixth day died of unmistakeable symptoms of embolism. One of the physicians, a strong nonconformist of this kind as to ovariotomy, chloroform, &c., in the absence of the other Medical man, laid all the blame of the death at the door of the chloroform, which was eagerly agreed to by the saddened and broken-hearted husband and sorrowing friends; yet nothing could be more unfair to the absent administrator of the chloroform, or to this agent itself. This ill-judging but leading obstetrician did not care to know that all traces of chloroform in the blood disappear in less than six days, nay, in much less than six hours, and that it was quite impossible that chloroform had anything to do with the sad event in this case.

There is, as a fact, every reason to believe that there has not been one single properly-attested case of death from chloroform in midwifery practice. This is due, in a large measure, I think, to the unusual activity of the respiratory and abdominal muscles during active labour; where, however, there are signs of weakness, it is always due to the coincidence of uterine hæmorrhage post-partum. I have been told of late of two cases of ruptured uterus where chloroform seemed sensibly to diminish the bad effects of the "shock," and all the best opinions I have been able to obtain agree that the convalescence after chloroform is always better than where it is not used, and that it in no way favours hæmorrhage. As an instance of the crude and saddening opinions of some men, I may cite this case:—

Mrs C.—I was called to this lady suddenly one morning about four o'clock, at Pimlico. I was to administer chloroform as she and her husband wished it; but some leading Medical man had shrugged up his shoulders, and told her he would not advise it on any account—that pain was a natural ordinance in labour, &c. The lady was in active labour, a half-witted old family servant assisting as nurse in a very primitive manner. If I did not give the chloroform I was told they would send for a dentist! opposite, who was known to be an adept in that way. I never felt so degraded; she laughed and groaned at the dogma of the St. George's Hospital authorities-obstetric who made pain a natural ordinance or stimulus; she had learned the practical fact that there had not been one accident from chloroform in labour, and that it saved pain; this was enough for her purpose.

Mrs. B.—This case was in every way very similar. The lady had heard all the objections against chloroform, but "convinced against her will she was of the same opinion still," that she might take it. Resident in London, she had not had a child for six years, and she was not far from forty-five years of age (when women suffer so much), and her labour was, indeed, up to a certain point, attended with much pain. But my surprise was great on arriving at the house to find that the lady had, unknown to her Medical attendant and friends, sent to Edinburgh direct from London for a pint bottle of chloroform, which she drew from under her pillow, requesting me to give it all if necessary. She was four hours under the chloroform, and made a far better recovery than in any former labour without it. I am almost certain if I had not arrived in time, she would have prevailed on her husband or nurse to administer it. Some leading obstetricians had said it was a demoralisation for a "high-born damsel" to take chloroform, but she couldn't see it. She was told it ought to be an indictable offence to give it, as these authorities held, but of this she too was apocryphal. I have been asked, whether I would recommend chloroform where there had been *epilepsy* or puerperal *mania*, previously. In the former class of patients the anæsthetic is directly beneficial; in the latter it requires much more circumspection. I now forbear to specify common cases of "version," where it is exhibited so often. I believe, too, that even where there have been paralysis and

apoplectic symptoms, an operation without chloroform would be more dangerous than with it.

Mrs. H.—This lady has had eight children. Very decided puerperal mania with some of them, and chloroform only with the later children. With this short history, and a very vivid caution or statement that she would take none but homœopathic remedies, and no opium or morphia on any account, I found myself attending her late one night this year, near Westbourne terrace; much inertia of the uterus, much tendency of homœopathic friends to blame the chloroform; much inertia of the uterus, requiring ergot and the chloroform alternately. Eager incoherent asking for more and more chloroform, which, however, I managed not to give till the os had been dilated to the size of a shilling: the case progressed well, but on the fifteenth day puerperal mania made its appearance. The husband and friends were now blaming the chloroform, and anxious for treatment by globules; but, by a little pious fraud, after two nights dreadful raving and want of sleep, a full dose of Battley was prescribed with hyoscyamus. I had to write two prescriptions, one to show the lady herself and husband, in which Battley was conspicuous by its absence; the other sent to the chemist, in which it was present: such is the deplorable pass to which prescribing has now come in England by the quackeries of the day, and the foolish agitation to have prescriptions written in English, espoused by journals in the interest of the chemists' shops; such the direful effect of the over-dosing chemist system; such the chief reason, I think, why globulism prospers, and young and honest Medical men in vain strive against it. I am quite sure the chloroform was of immense benefit in this case, that it rather prevented the mania for a time, yet, without morphia, the case would have ended badly. Three cases of apparent death from chloroform frightened me very much during the last two months, but in each the Faradisation, or rhythmic electricity, to the phrenic nerve acted like a charm. I was not giving the chloroform myself, but was standing near, und asked to assist in the resuscitation. I know nothing at all to be compared to it for setting up artificial respiration. The effect is quite beautiful. But I do not think it is understood, or held ready in more than one of our twenty operating theatres in London. It has been tested over and over again in hundreds of animals lying apparently dead from chloroform: it is a measure of infinitely more importance in cases of chloroform apnœa, apparent death from drowning, &c., than the too often imperfect directions of the Royal Humane Society, copied year after year for twenty years, as to the "ready" method, pronatic respiration, &c.

In puerperal *convulsions* there is no remedy at all equal to chloroform, yet the older practitioners, who still believe in the lancet, are slowly brought round to this more rational treatment—the homœopathic practitioners have us "on the hip" in these cases, as they give chloroform, and are perfectly cognisant of the chaos now working in our ranks by a sort of Fetish worship or prejudice in favour of the lancet and against chloroform: quacks of all kinds wish for prescriptions in English also, so as to lessen the respect in which the more rational men are held. False stories as to chloroform used by thieves for highway robberies, encouraged by such shallow writers, now recoil on their authors. But chloroform has, probably, never been so employed, and we have been giving it a bad name which it never deserved; but, like "fever nests," or other jobbery, it has served its purpose as a "sensationalism."

A very unusual and suggestive coroner's inquest, in which an experienced knowledge of anæsthetics was called for, came under my notice a year or two ago, one in which the very existence of the family of a Medical man, recently deceased, was deeply involved. The story, in a few words, was of this nature:—

A Medical man in considerable practice, subject to intense fits of neuralgic pain, died rather suddenly from some obscure cause. His life was insured for his family for some small amount, and the insurance office disputed the payment. A *post-mortem* was called for, all the familiar signs of chloroform poisoning — congestion of right side of the heart, peculiar state of lungs, smell of chloroform, &c., were all absent. Yet some experts, medico-legal, on the part of the office, gave an opinion, on account of sundry bubbles of air found in the veins and sinuses of the head, that the case was a probable one of poisoning of a suicidal nature by chloroform.

My opinion was asked on the general result of the coroner's inquest, and, after consulting my excellent friend Dr. Wilkes, of Guy's, Dr. Richardson, Mr. Callender, of St. Bartholomew's, and one or two other men all well versed in the details of dead-house examinations, this interesting fact was elicited—that bubbles of air found in the veins and sinuses of the head depend solely on the manner in which the calvarim is taken off. A leading Medical journal gave favour to the dogma that insurance offices are always right, and chloroform wrong, that the bubbles were of chloroform, though it subsequently transpired that chloroform had never been used at all!

All these cases I may say, in conclusion, demonstrate that we have sundry prejudices against chloroform to raise up our voices against, if we desire to uphold the dignity of legitimate practice, and that our manipulative skill is sometimes severely tested.

SCIENTIFIC ARTICLES.

ON THE DETECTION OF ACONITE BY ITS PHYSIOLOGICAL ACTION; BEING NOTES OF EXPERIMENTS MADE IN CONNECTION WITH THE TRIAL OF DR. E. W. PRITCHARD.

By FREDERICK PENNY, F.R.S.E.,
Professor of Chemistry, Andersonian University, Glasgow,
and
JAMES ADAMS, M.D., F.F.P.S., Glasgow.

The recent trial of Dr. Pritchard for the murder by poison of his wife and mother-in-law, is likely to take a high place in the *causes célèbres* of this country. Irrespective of those circumstances which distinguished the crime as peculiarly cruel and revolting, there existed in the singular combination of poisonous agents employed, and in the means used for their detection, considerations of special interest to the Medical Profession; and it is with the view of satisfying the numerous inquiries which have been addressed to us that we have prepared the present communication.

Besides conducting an independent examination of the organs of both ladies, similar to that committed to Dr. Douglas Maclagan of Edinburgh, and the results of which are fully described in Dr. Penny's reports to the Crown, and read by him in giving evidence at the trial, there was entrusted to Dr. Penny another, and a very extensive and difficult, investigation. He was required to report upon the nature and properties of a large number of articles of food—of various substances, labelled to indicate that they were officinal preparations of well-known drugs—and of various other articles, regarding the nature of which there was no clue. These were not delivered at one time, but were brought at irregular intervals up to a date very shortly preceding the criminal trial.

Among other articles undergoing examination, there were several phials, some of which were labelled and some not, containing "Tinct. Conii.," "Tinct. Digital.," "Tinct. Hyoscy.," "Tinct. Aconit.," "Battley's Sedative Solution," &c., &c., all of which were clearly and satisfactorily identified. The contents of the phial labelled "Battley's Solution," which, as shown at the trial, had been found in Mrs. Taylors pocket, was tested for mercury, antimony, and various other metallic poisons, and the results showed the presence of antimony in a soluble form, in the proportion of one grain and a half of tartarized antimony to the fluid ounce. The discovery of an extraneous admixture directed special attention to this Battley's solution, which we shall hereafter call "Pritchard's Battley," and led to its chemical examination for the leading organic alkaloids, other than those existing in genuine Battley. After a fruitless search

: the presence of strychnia, veratria, conia, and hyos-
amia, a small quantity of the liquid was evaporated in a
tch glass, and the soft extract applied to the tip of the
ngue, when there was felt quickly supervening upon the
te of *genuine* Battley's solution a peculiar benumbing
l tingling sensation, increasing in intensity for a short
ie, and persisting for some hours. In numerous com-
ative trials with genuine Battley's solution, obtained
n various sources, it became very clearly evident that
re was a something characteristic in the taste of the
tchard Battley, and suspicion turned to the probability
an admixture of aconite. Observations made with an
porated soft extract of Fleming's tincture of aconite,
h and without a mixture of genuine Battley, gave sen-
ons so perfectly corresponding, that strong presumptive
lence was now obtained of the presence of aconite in
suspected fluid.

y Stas's well-known process, and by other chemical
ns, more distinct indications of aconite were obtained ;
the unreliable and altogether inconclusive character of
known processes in chemistry for the detection and
quivocal identification of certain vegetable poisons,
cially when contained in organic mixtures, and also the
essity of husbanding what remained of the suspected
id, were sufficient reasons for determining that no time
material should be wasted in further chemical analyses,
a series of experiments upon animals was therefore
rmined on and planned.

t was at this stage of the investigation that Dr. Penny,
ing that he would not be able, unaided, to overtake so
nsive an inquiry, owing to the limited time at his dis-
al, and having a part of the analysis still on hand, soli-
d the assistance of Dr. Adams. Ere this date, however,
list of witnesses against the prisoner had been closed
served, and hence Dr. Adams was precluded by the
utory limitations from appearing in evidence at the
l.

n publishing the notes and results of our observations
experiments, we wish it understood that we do not
m for them the character of a scientific or complete
siologieal investigation. They are intended simply to
vey to the Medical Profession such details as may show
practical nature of the inquiry which we conducted,
at the same time enable a judgment to be formed by
ers as to the value of those conclusions at which we
ved as a result of that inquiry.

/e have also to add, that the very limited time at our
mand before the trial, debarred us from attempting an
ustive physiological course of experiments, and at the
time prevented us from making microscopic exami-
ns, analyzing the blood, &c., &c.

view of the fact that different kinds of animals are
rently affected by the same agent, we resolved to res-
our observations to one class, and several satisfactory
iderations led us to select the rabbit. It appeared to
little moment, that the phenomena manifested in our
s with the rabbit should differ from those exhibited by
uman subject when under the influence of the same
t. For our purpose it was sufficient if the action of
oxic agent was uniform and characteristic, when em-
d on the same animal.

r object in these altogether practical experiments was
old—first, to determine if the suspected liquid con-
d anything destructive to life, when employed in a
which would have been safe, assuming it to contain
reign substance ; and second, to determine what that
n substance was, of the presence of which we were
ly clearly satisfied.

e details of these experiments, although somewhat
us, can scarcely be omitted without a corresponding
f practical usefulness. For that which may seem un-
rtant to one observer, and perhaps only casually intro-
l in the record, becomes often to another the single or
gest point of interest, and the clue which may lead
r to separate investigation or to another conclusion. It
: sufficient, unless for popular comprehension, to state
certain agents are destructive to life in certain doses,
hat paralysis or convulsions is a common effect ; but
for satisfactory reference and comparison it is necessary to describe the extact form in which the agent has been employed, and the order and precise nature of the phenomena observed.

For several sufficient reasons we thought it advisable to make a number of concurrent experiments with atropia, veratria, conia, hyoscyamia, strychnia, digitalis, &c. ; but as these do not properly come within the scope of our present communication, we shall not allude to them further than to say that some of them proved extremely interesting ; and as our inquiry widened, there grew in our minds a conviction that the physiological test in its application to the detection of vegetable poisons presented a more inviting field for toxicologists than had hitherto been admitted, and we hope at another date to present some of the conclusions we have reached regarding certain of the alkaloidal poisons. Meanwhile we restrict ourselves to the special investigation of Pritchard's Battley. The agents we employed were—

1. Genuine Battley's solution of opium procured from Murdoch Brothers, and taken from the same stock bottle out of which the phial containing Pritchard's Battley was filled.
2. Tincture of aconite (Fleming's).
3. Mixtures of tincture of aconite with genuine Battley in various proportions.
4. Pritchard's Battley.

These agents were prepared for the purposes of experiment, by being evaporated, either at a gentle heat, or by evaporation *in vacuo* over sulphuric acid, to a soft extract, which was then disolved or suspended in a measured quantity of pure water.

In a number of experiments, the extract preqared from genuine Battley, and that from tincture of aconite, was either introduced into the stomach or dropped upon the eye ; but while the characteristic effects were unequivocal, we were satisfied that so much more agitation and alarm were produced by the greater and more prolonged handling of the animal, that we soon abandoned this mode of operating. Moreover, we found that the quantity of the agent required to produce the same effects was more variable—the interval occurring before the symptoms became manifest more uncertain, and the duration of the experiment prolonged to so tedious a degree, that observation became difficult and less reliable. To these experiments we therefore only refer as corroborative of the phenomena otherwise generally observed.

In the very large proportion of instances we injected the agents beneath the skin, selecting the fold of integument at the flank or between the skin and muscles of the back. In this operation we employed a small graduated glass syringe, armed with a needle, perforated through its entire length ; taking care in every instance to avoid injury of the large vessels and nerves, or penetration of any of the cavities.

This method of hypodermic injection is almost literally painless, and in execution is easy, rapid, and complete, while the action of like quantities of the same agent is better contrasted as regards the time within which the characteristic effects begin to be noticeable. These variations were generally within small limits, and seemed to bear a close relation to the age and strength of the animal.

Of the facts observed in our experiments we shall now give a summary, referring for more precise details to the Appendix, where we record such a selection of experiments as will indicate the general character of the whole.

Genuine Battley's Sedative Solution.

In one instance ten grains were introduced into the stomach, in another, 100 grains were employed. The quantities injected under the skin varied from ten to fifty grains. In no instance did death occur.

Within ten minutes of the introduction of the poison by injection under the skin the animal seeks a prone position, lying fully extended on belly and chest—the head resting on the ground—the legs sprawling—the claws concealed. If undisturbed, it inclines to retain this position, rarely shifting its place or attitude. When urged to motion, it crawls a few paces in a tortoise-like manner, but speedily subsides into its former passive, motionless condition. When lifted by the ears it struggles, and when laid on its side it recovers

its legs. A sharp noise or heavy footfall attracts its notice. The eyes remain open, and only tend to close at occasional long intervals. The pupils are dilated. The respiration is slow and gentle. In from five to eight hours the effects begin to pass away, and in about fourteen hours the animal eats freely, and exhibits vivacity in its movements.

In carrying out these trials with Battleys solution, an impression gained force in our minds that there is still much knowledge to be acquired, and much of error to be removed regarding the action of the nervine poisons generally. We are led, therefore, to request particular attention to the fact that no convulsions, or tendency to such, was exhibited in any of the animals experimented upon with Battley's solution. This is opposed to common belief, for, without specifying names, we may simply observe that every authority we have consulted mentions, in express terms, the occurrence of convulsions as a usual and characteristic action of opium in mammiferous animals, and in many instances rabbits are referred to as among the animals subjected to experiment. Such a mistake, as we hold it to be, may be accounted for in part by the circumstance that authors of systematic treatises cannot reasonably be expected to verify, by personal experience, the statements of observers of good repute, from whose writings quotations are usually made. Re-copied and re-transferred these statements are at last, in many instances, accepted as beyond cavil. In the case of opium, familiarity with the drug and the usual faithful description of its ordinary effects on man, have probably assisted in securing a too hasty acquiescence in the common statement of its effects on animals. Be this as it may, we have satisfied ourselves that, as regards rabbits, no convulsive seizures attend the action of opium. As Battley's liquor is a watery solution from which a certain portion of the drug is excluded, we made three experiments with laudanum, a soft extract of which, prepared by evaporation, as in the other instances, was employed. In one case we injected the extract of twenty grains by weight beneath the skin of the back of a six weeks' rabbit; in the second fifty grains, and in the third one hundred grains, in both cases on full-grown rabbits. The effects produced were identical with those caused by Battley's solution, with this exception, that while there was an equal indisposition on the part of the animal to move its position until stimulated and urged, there was a difference in the character of the progression of the animal along the floor. Under laudanum the animal moved with its customary leaping action, and seemed to have entire power of its limbs, while Battley's solution induced a condition in which the movements were of a crawling nature. But in no other respect was there any contrast.

Tincture of Aconite (Fleming's).

In one instance five grains, and in a second seven and a half grains, were introduced into the stomach; the animals recovered. Fifty grains introduced into the stomach caused death in fifteen minutes. Half a grain dropped into the eye produced all the characteristic effects. Two grains injected under the skin resulted in recovery in one hour fifteen minutes, and four grains applied in the same way caused death in three hours fifteen minutes.

The symptoms vary in the order and in the rapidity of production according to the strength of the dose. In a case proving fatal, and where there has been time for the development of the effects, there is first an interval of restless uneasiness, during which the animal shifts its position, and occasionally couches, with one or both hind legs extended laterally. It remains for a short interval in an attitude of expectancy or watchfulness, during which a twitching of the lips and a chewing action of the jaws is observed. Gradually the limbs become awkwardly stiff—the claws protruded, and the feet sprawling, as if grasping the floor—the animal seemingly steadying itself. The head is carried erect and somewhat retracted—the nostrils expanded. Occasionally spasmodic movements of the ribs and belly occur as if retching.* Suddenly the animal staggers and rolls over, quickly regaining its feet. Saliva begins to flow from the mouth, and soon after peculiar chirping or stridulous cries are emitted. The severe convulsions which quickly and invariably follow, are of an opisthonic character, the limbs being extended in a straight line with the body—the back arched, and the head excessively drawn back. In a few seconds the convulsions subside, and the limbs become relaxed, the animal lying helplessly on its side. After a longer or shorter interval, it is then occasionally affected with an impulse to rush madly forward or make violent leaps, without regard to obstacles; but the motions are of an abortive paralytic character—the legs sprawling about in a floundering, jerking sort of action, altogether different from the usual leaping motion of the animal. After one or more convulsive seizures, it lies on its side with head retracted—nostrils distended—flanks heaving—the forepaws spread apart and held in the air. The respiration becomes very evidently laborious, is quite audible, and seems altogether diaphragmatic or abdominal. In this utterly helpless condition it is still sensible to stimuli; it winces when the cornea is touched, and is roused to momentary effort on pulling or squeezing the ears, legs, or tail. Salivation continues, but no longer accompanied by the twitching, chewing movements; the eyelids are half-closed or drooping; the pupil usually contracted. In this prostrate state, an interval of many minutes, or even of some hours, may elapse, during which occasional convulsive seizures may occur. Frequently, at the termination of such seizure, the urine is forcibly discharged. At length a strong convulsion takes place, and the animal dies. The limbs immediately relax, and the pupil begins to dilate. *Rigor mortis* is nearly complete in from forty to sixty minutes.

Genuine Battley's Solution and Tincture of Aconite.

Fleming's tincture of aconite was mixed with genuine Battley's solution in proportions varying from one of the former to from four to eighteen of the latter. In one instance death was caused by one grain mixed with nine; in another, two grains mixed with ten. In both instances the poison was injected beneath the skin.

There was caused by a mixture of these agents an evident blending of the symptoms produced by both, but the action of the aconite predominated. When, however, the Battley was employed in the large proportion of eighteen to one of the aconite, the conditions were reversed. When a full dose of both in a state of mixture was used, there was at first less of the active uneasiness than was noticed with the aconite alone, on the contrary, a stronger disposition to couch or rest was manifested; but when doing so, the head was invariably carried erect. On being urged to motion, the hobbling or crawling progression, as opposed to the spasmodic jerking action observed with aconite, was more strongly marked. The convulsive seizures did not, however, seem to be lessened in severity, but the intervals of relaxation were longer, and during these intervals the action of the Battley became evident.

Pritchard's Battley.

The symptoms are so closely similiar to those of Battley's solution mixed with aconite, that, *nomine mutando*, the one pass for the other. No possible distinction could be drawn from the appearances presented by an animal suffering from the effects of a dose of Pritchard's Battley and of another undergoing, at same time, the effects of a mixture of Battley and aconite.

We think it preferable to indicate thus shortly the action of Pritchard's Battley, instead of summarizing its effects, as we have done with aconite and Battley's solution respectively, because, in all experiments wherein vital action is exhibited, there will invariably be found some points of difference in the occurrence, order, or character of individual phenomena. We trust that the description we have given of the effects of aconite and of Battley's solution, when used alone, is sufficiently clear for the purpose of comparison and reference; and with that circumstance kept in view, we believe that the larger number and fuller details we have given, in the Appendix, of experiments with Pritchard's Battley, will enable our readers better to appreciate the nature of those points of similiarity by which we ourselves were satisfied regarding the composition of Pritchard's Battley.

* A rabbit does not vomit.

Referring, for example, to experiments No. 27 and No. 4, it will be seen that, although there was a difference in he strength of the animals operated on, probably also in ie dose of the agent employed, these influencing, no oubt, the duration of the experiments, there was yet such close correspondence in the general effects that no essen- al difference in the character of the phenomena can be edected.

Having thus by clear and satisfactory evidence established ie characteristic and essential differences in the effects oduced on the rabbit by genuine Battley and Pritchard's attley respectively; and having found that the action of ritchard's Battley in a fatal dose corresponded in every spect with that of aconite, either alone or when mixed ith genuine Battley; and bearing in mind the peculiar id distinctive sensation communicated to the organ of ste by the above liquids—we had no hesitation in arriving the following conclusions:—

1st. That Pritchard's Battley contained a poisonous sub- ance.

2nd. That that poisonous substance was aconite.

We may also state, that from a careful consideration and omparison of the intensity, the period of access, and the uration of the symptoms exhibited in our trials with the ixtures of aconite and of Battley's solution in known uantities, we were led to infer that the proportion of the rmer in Pritchard's Battley was from five to ten per cent. 'e disregarded the infinitesimal proportion of antimony scovered in Pritchard's Battley, being satisfied that it uld not in any way influence the symptoms we witnessed. Our conclusions were confirmed by the fact of our finding effects analogous to those of aconite produced by any of e other agents (veratria, strychnia, &c., &c.) employed by s in the concurrent experiments already referred to, or by ıy other poisonous agent with the action of which we ere familiar.

With the Medical aspects of the criminal trial our inquiry id no necessary connection, and we, therefore, purposely oid any commentary on the peculiar symptoms mani- sted by Mrs. Taylor and Mrs. Pritchard. Neither have e attempted to draw any analogy between the action of ıe poisonous agents as displayed upon animals and those roduced on the human subject. These considerations rm sides of the case altogether apart from those which e attempted to uncover, and were otherwise dealt with the special Medical and general evidence. That the ıfortunate ladies were poisoned was clearly proved, and e prisoner ultimately admitted that he did put aconite to the Battley's solution. The detection of that aconite ıs the problem that our experiments were intended to lve; and although the confession of the criminal has no ubt aided the complete acquiescence of the public in the stice of the verdict, yet his admission or denial could not any way influence our convictions, nor the conclusions which we had already committed ourselves.—'Glasgow edical Journal.'

[This paper was accompanied by a series of selected ex- riments, illustrating the general conclusions arrived at Professor Penny and Dr. Adams.]

CYCLOPS' TWENTY-EIGHTH LETTER ON PHYSIOLOGY.

To Vigilans.

SIR,—Has physiology clearly defined the true meaning, wer, modes of secretion and uses of a gland? This bject has always appeared to me to be very much con- ed, for instance, the liver is called a gland; but if a ivary gland is compared with it, what a wonderful ference there is between them. The one, the liver, has fatty surroundings, while the other is embedded in it. hink we should be equally justified in calling the lungs, pair of air and blood glands, as we are in calling the er a simple blood gland. We see that the lungs are as e from fatty envelopments as the liver. What can all the fatty matter have to do with the salivary glands and why should they be so embedded within this structure, while the liver and the lungs are kept entirely free from it? Let us look also at the kidneys. They are always embedded in a large quantity of fatty structure. Are we right in calling them glands? They differ amazingly in their action and duties to the salivary glands, as much as both these classes do from the liver. If all of them are to come under the designation of glands; they must be divided in some such way as this:—The liver is a blood gland without fat and a simple receiver of venous blood, from which by the assistance of its own structure it extracts a fluid called bile, to be used again in the body, but getting no benefit from any fluid or element which fat or any other organism can supply. The salivary glands are organs embedded in fat and secrete a fluid, varying much at different times in its chemical character. But then the question arises, what is the use of the fat round and about them? Has the fat anything to do with their functions or their secretions, for it is very evident that it would not be there except for some wise and useful purpose and as it always is there, we ought to conclude that there must be some reason for it. The saliva or natural secretion of these glands is an element formed in large quantities to be used again in the economy of the body. The next organs which are called glands are the kidneys which are also embedded in fat. Now, these secrete from the blood the element called urea and probably some other elements along with it, for the immediate purpose of excretion; so that they should not get back into the system. But along with this urea and other matters, there is a large percentage of fluid. Physiologists have been accustomed to teach that this also is eliminated from the blood. But here arises a serious question, seeing so much fat about them; has it anything to do with the secretions of the kidneys. Now here we have three very distinct facts, which I am inclined to think have hitherto been very loosely thought of and as unphilosophically explained. A gland without fat and a mere converting organ; glands with fat and highly secreting organs; and two other so-called glands which are simply excreting organs. The first and solitary one deriving no benefit from fat, as it is not there, and the two others having immense fatty surroundings with what must strike every one some use to be derived from them; yet these latter are of totally opposite uses and characters. We naturally ask, can they be continued to be classed in the body as they have been? The next question naturally arising out of these considerations is, what can be the use of the fat in the two last so called set of glands, the salivary and the kidney, and why has the liver none? Perhaps there is no organ in the body that has, *per se*, been so much written about as the liver; or has had so much consideration given to it, or the universality of disease of every kind, sort and character, functional as well as organic, been attributed to it, as well from its secretions as its non-secretions. These facts are not alone confined to the British Islands or wherever the English, Irish or Scotch settle, but even in foreign countries, so that the French and German schools do the same as we do and attribute the largest percentage of disorders and diseases to which the body is liable to the poor liver or its secretions, whilst every imaginable drug administered, seems designed for, or is supposed to have some action thereon, whether it operates on other organs or not. This infatuation may be said to be so universal, as to amount to as complete a monomania of the whole Faculty, as any poor fellow who struts about and imagines himself a king. Now here is a viscus, one of the largest in the body, which, as I cannot designate it as a gland, I will simply call it a blood converting organ. Its anatomy is of the simplest character as well as its duties. It is fleshy and porous, not quite so much so as the lungs. It has few arterial vessels going to it and those which can only support its structure; but all the venous blood of the abdominal organs is emptied into it; which with what it makes itself, it uses in its soft structure to make or rather to convert into bile. The residuary mass from this, is even then small, and goes into the vena-cava and so helps slightly as a diluent to the new ingesta, along with residuary

venous currents from the upper and lower extremities. I have said in a former letter and it well bears repetition, that if venous blood, well charged with biliary elements goes to the liver, that organ is safe to extract them, but if these elements are deficient, how can it take anything from nothing? Are we then to attribute a clayey stool to a sluggish liver? This dogma or infatuation seems to have seized everybody's mind without thought, sense or reason. Why not go deeper into the matter and attribute it to want of the elements from which bile is made. I can give myself a clayey motion at any time, by taking an opium pill for any flatulent or colicky pain; but I do not for a moment accuse my liver of derilection of duty. As long as my pains continue, from whatever morbid cause, so long will I endeavour to stop them. I will not suffer a moment's pain if it is in my power to subdue it; it would be less than human if I did. Some action which opium always produces, has arrested or caused in some way the properties of bile in my abdominal venous blood to become diminished, but very soon afterwards, Nature having had time to get into a right tract again, I find biliary stools; but I never blame my liver. Again, if the liver has excess of elements sent to it, it naturally makes excess of bile. Are we to accuse the liver again of mala-praxis? If there is excess of bile then at any time, it is from excess of material and if there is a deficiency, there was nothing to make it from. If people with a richness of biliary secretion, diet or starve themselves, as they often do; they bring on certain discomforts and lay them all to the poor liver; when a good solid meal would be the best cure for them. Why not give the bile its proper employment: for if this is not done, it runs off in a diarrhœa, and if there is not sufficient bile there is in my opinion some error in the first cause and not the second. I believe the liver to be a simple and an industrious organ in itself in all its duties and actions and reflecting on the ill usage it has received from everybody, I often think that I am the only friend it ever had. Now I have abundant reasons for all I say on this subject and these have arisen and been confirmed in me from my investigations of the colon, I have often thought that the Faculty, taking them *en masse*, have considered the body but as one huge liver and have believed that all diseases arise from it alone and that such a viscus as the colon never existed in it. As the ghost in Hamlet says, "I could a tale unfold," and I am quite prepared to do it, if the thousand mistakes which are made every year in diagnosis and all the blame laid to the poor liver which it never deserved. It has been one of those misfortunes to the system, that the colon is what it is and that it traverses the space it does and has its various juxta-positions to other organs. Thus, for instance, if my readers have studied the colon in its anatomical and physiological uses, as I have laid down for it, they will have perceived that the angle of the ascending and transverse portion lies exactly upon a part of the liver. Therefore, without thought of the colon at all, the great fault of the physician seems to have been to consider pains, enlargements, and great sympathies in this region as affections of the liver. I have said that Nature has designed the fæces for vital purposes, hitherto not admitted into the philosophy of Medicine, and that she causes or induces a sacculated condition of the colon to retain them. Now, she does this very frequently in the part opposite or in juxta-position to the liver as often as anywhere, and these cases, if they were not so serious, that is, really not serious of themselves, but made so by the Faculty they would afford much food for laughter. It so happens that I have had many cases of this kind before me and as it is not orthodox to mention names, there are scores of our physicians and surgeons now living who have committed themselves to opinions, which, if they had studied the colon more they never would have done, and the mere explanation of these facts may be a great guard to them in future. I will mention one or two cases in point which must suffice for the present.

A lady, aged forty-two years, mother of twelve children, had a lump come on her right side, just about the place where the angle of the colon lies upon the liver. The best general practitioner and physician of a large provincial town attended her. They both pronounced it tumour on the liver; she was mercuralized as a matter of course, she was duly leeched, blistered, and poulticed, and iodined. Months passed away and she was no better. A change of circumstances in her husband's affairs brought her to town. Here some of the first men at the West End of London were consulted, all declared the same thing, there was not the slightest difference of opinion. Tired and worn out by physic and external applications, and somewhat broken down in health, she went down to a hydropathic establishment in the country. The principal there concurred in opinion with the diagnosis already given. But the treatment here was simply devoted to restoration of health, as much exercise as could be taken and as much good diet also. Not being considered entirely hydrophobic, she found she could not do without her sherry, and so she had it. One morning, without any cause she had a large stool, then another, and in the evening another, and about the second day after this, she was placing her hand on her sore side, as she called it, and found, to her great surprise, the tumour gone! As she was getting stronger she left, and afterwards from her sixth completed her number of twelve children; but always found a tenderness over this spot, and it was for this only she consulted me. Having the opportunity of explaining her case, she, for the first time, found out what had been an enigma to herself, her husband, her friends, and her doctors for many years, that it was a simple collection of fæces from a sacculated condition of that part of the colon. Fæces had passed the spot leaving the old mass there for very many months. In short, it was no tumour at all.

One more case similar to this, a gentleman had precisely the same sort of thing and consulted several of our first surgeons and physicians, and he named them all to me. "Oh," said one surgeon in great practice, "I have seen many of these cases. It will not come to anything; sometimes I have known them disperse, but it will not get larger. I will read you a few cases I have had. I keep them under the head of 'simple tumours of the liver.'" So he consoles the patient with these, and gives him directions how to act. Another surgeon saw it, "He did not think it was on the liver but behind it." Another said, "It was on the intestine itself." Well, that was a very near guess! A physician saw it and could not make it out at all, and so he asked him to call again by appointment to meet a friend of his, another physician. These two spent a long time over him, and then dropped, of course, into the conclusion of Mr. ——, the surgeon of whom they both had the highest opinion. Another physician knew all about it at once, and said that, that was a subject to which he had paid great attention, and, in fact, he was going to lecture on it that very day, and asked the patient to accompany him, which he did, and heard an hour's discourse, but making neither head nor tail of it, packed up his carpet bag, and went off to Germany the next day. He consulted a German doctor, who very wisely told him it was a decided case of dislocated kidney, which had shifted to that position. This determined him not to medicate any more. He said after he had been in Germany about a month, taking all the exercise he could and living on light diet and light wines, he woke one morning and found his so-called tumour gone. In another fortnight he returned home, went first to one of his physicians, "You are wrong, doctor, this time, I'll trouble you to find my tumour." "What did you do?" "Nothing, I only got up one morning and found it was gone." He went to another, then to a third, then to his surgeon. None of them could make it out. I drew his attention to certain facts of the case, and he has not the least doubt, any more than I have myself, but that it was a collection of fæces in a sacculated part of the colon at that spot, of which I have seen scores.

In mentioning these facts connected with the liver, I do it for two reasons, first, because I believe the liver a much maligned viscus, and, secondly, because there is less known of the colon, its diseases, and its physiology, than any part of the body, and, thirdly, to put very talented physicians and surgeons on their guard against mistaking simple sacculated states of the colon with fæces, for tumours, espe-

ally in that part opposite the liver, and I would suggest note-takers, who have many cases of this kind booked, t to credit any of them unless they have made actual st-mortem examinations and *found them*. Thus, while ture herself is bountiful to man in often conserving the wels, she does this act wisely and at all times well, when colon has never been tampered with by Medicine. But, the other hand, when mercurials have been constantly ministered which have tended rather to the enlargement the liver, than any good ever got from them by that an; they have on the other hand, together with aperients relaxed the muscular fibres of the colon that when Na- has endeavoured to conserve the fæces, some parts of colon have become sacculated by them and factitious ups have been formed along its course which are mis- en for tumours. Many of these facts would form very ious episodes of the Ars Medicinæ.

I am &c., CYCLOPS.

he Editor begs to state that he does not hold himself in any way onsible for the opinions expressed in the foregoing letter.]

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 7TH, 1865.
DR. PEACOCK, PRESIDENT.

Mr. ADAMS and Mr. CARR JACKSON exhibited specimens

TWO TUMOURS CONNECTED WITH THE HUMERUS,

ch had necessitated amputation at the shoulder-joint. Mr. Adams's case the patient was a young married man, three months gone with child, and the tumour arge size, with an extensive connection with the bone, of a soft encephaloid character. The malignant nature he tumour was verified by microscopic examination. peculiarity of this specimen was that it exhibited striæ, the admixture of muscular fibres, in various stages of eneration. The operation was successful, and there has no recurrence hitherto.

Mr. C. Jackson's case the tumour was removed from a aged fifteen. It was only of four months growth. There much fibrous tissue mixed with the proper structure of growth, the nature of which appeared to be of osteoid er. The patient recovered.

r. HOLMES showed a specimen of

A TUMOUR OF THE ARM OF MALIGNANT NATURE,

large cysts growing from the soft parts of the arm be- he deltoid, and encroaching on the shoulder-joint, the s and axillary vessels being expanded over the chief The patient died on the fourth day after the opera- apparently of fatty degeneration of the heart, but no mortem examination was allowed.

. HOLMES likewise showed two specimens of

SUCCESSFUL AMPUTATION AT THE HIP.

e, an adult, the disease was recurrent fibroid tumour thigh. The other was a case of entire inflammation -myelitis) of the femur after excision of the hip.

HOLMES also exhibited

UTERUS, AND A LARGE SOFTENED FIBROID TUMOUR

had been removed in mistake for an ovarian tumour. eculiarity of the case was the large amount of fluid ned in the tumour, and the absence of uterine sym- . In this case the tumour had been twice tapped, s much as a gallon of fluid evacuated. The patient een at an earlier period under Mr. Spencer Wells's when the disease has been diagnosed as three fibroid rs attached to the uterus, which was really the case. normous growth and softening of the uppermost of umours, together with the absence of uterine hæmor- and the apparently healthy condition of the os, had the mistake. The operation was fatal, the intestine been injured in breaking down the adhesions, which xcessively numerous and firm, the mesentery and ntestine being almost imbedded in the tumour. The with two fibroid growths and the stalk of one re- was also exhibited. The tumour removed was of very great size, spongy and reticulated in texture, and attached to the uterus only by a stalk about the thickness of the thumb.

Mr. BRYANT instanced a case which had been examined at Guy's Hospital, where a fibro-cystic degeneration of the uterus had so closely simulated an ovarian tumour that it had been so considered by all who had seen her. The woman had been admitted in a moribund state. Mr. Spencer Wells had referred to a similar case.

Dr. GRAILY HEWITT remarked that the condition of the os uteri had no great value in diagnosis of such tumours. The use of the uterine sound, he thought, would have thrown light upon the diagnosis.

Mr. BRYANT showed a specimen of

HYDATID OF THE BREAST

from a married woman, aged thirty, who had suckled several children, and had suffered for some years from a painless fluctuating tumour in the breast. It was explored by a trocar and canula, a piece of membrane was drawn out, and then a free incision gave exit to the main wall of the cyst and some smaller hydatids.

Mr. BRYANT's second case was one of

HYDATIDS IN THE BLADDER.

The patient, a gentleman of fifty years of age, was suffering from retention of urine. He had had no gonorrhœa or other disease, but had had a previous attack of retention in 1851, in which no instrument could be passed, but he was spontaneously relieved a week afterwards, with no constitutional disturbance. The same thing again occurred about seven years afterwards. Some time after that attack he was examined by a surgeon, and pronounced quite healthy. A few days ago, however, similar symptoms manifested themselves. No catheter could be passed, and no urine voided. There was no constitutional disturbance or pain, though there was a large tumour in the lower part of the abdomen; this was not equal on the two sides of the abdomen, but more prominent on the right than on the left side. On examination per rectum, the pelvis was found filled up by an indistinctly fluctuating tumour. Attempts were made to pass a catheter, but in vain. Next day an attempt was made to puncture the bladder per rectum; but though three punctures were made the bladder was not reached. Then an incision was made from the perineum, and a small hydatid was evacuated. Next, the incision was extended into the rectum, and a large mass of hydatids was extracted, enough to fill a porringer. The cyst was so large that a catheter was passed up to its hilt in it. After this, with some manipulation, it was found possible to puncture the bladder, and a quart of dark-coloured urine was evacuated. An elastic catheter was fixed in the bladder. The patient was left relieved. (Two similar cases which had occurred at Guy's Hospital were then referred to.)

Mr. BRYANT also exhibited a

LARGE ADENOID TUMOUR

developed in the breast of a woman over seventy years of age. It was the size of a cocoa-nut, and contained numerous cysts. There were no enlarged glands, nor any constitutional disturbance. The tumour was removed, and proved to be of an innocent cystic nature. The interest of the case lay in the fact of the advanced age at which the growth commenced. The microscopic examination showed the tubular structure often found in the adenoid tumours of younger life.

Mr. WATSON showed the Larynx and Trachea from a case of Croup, in which tracheotomy had been performed.

Dr. CRISP wished to correct a report in the 'Lancet' of something which had fallen from him with respect to the cattle plague. He had been represented as saying that he had eaten a portion of meat from an animal suffering under this disease, and recommended it for public consumption. The latter part of the statement was incorrect. He had never advised that other persons should eat such meat, though he himself had done so by way of experiment.

Mr. Z. LAURENCE brought before the Society a patient affected, as he believed, with an entozoon in the eye.

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause, and have made such arrangements as will prevent the possibility of a repetition of the same. Any gentleman not having received his copy as usual during the last three weeks, will be kind enough to intimate the same to the Publisher.*

WEDNESDAY, NOVEMBER 22, 1865.

THE MEDICAL CIRCULAR.

THE RECOVERY OF MEDICAL CHARGES IN COURTS OF LAW.

It is a comparatively rare occurrence for members of our Profession to sue for the recovery of their charges in Courts of Law. The Fellows of certain Colleges of Physicians are restrained by their bye-laws from taking any such step; and among the rank and file there are not many who resort to law for a redress of their grievances. This abstinence from litigation does not result from any particular alacrity to pay doctors' bills on the part of the public, nor does it happen from the want of provocation to Medical men to take such a course, for unhappily there are few persons in any calling in life who are so shabbily treated by the world in general, or who devote so much time to gratuitous or ill-paid labour. The reluctance to enter into contests in the law-courts arises, we believe, partly from that generous and gentlemanly feeling which induces many of our brethren rather to forego their claims altogether, or to accept compromises, than to parade their wrongs before the world, and partly from the fact, that when Medical men trust to the arbitrament of a jury, their conduct and motives are generally misunderstood, and the result is a complete failure of justice, or, at best, a modified and doubtful success. The reason of this anomaly in our Courts of Law, in reference to Medical men, lies in the very nature of our Profession; and although judges and barristers, as educated and thoughtful persons, are often aware of the difficulty and delicacy of adjusting claims for Medical attendance, no such scruples affect the juryman, who is usually drawn from the trading classes, and who looks upon a professional man only as a trader, and to be dealt with accordingly. The Medical practitioner is, indeed, placed in a position of great comparative disadvantage in our Courts of Justice when suing for his charges. The clergyman, for instance, is never under the necessity of appealing to a jury, either to justify his theological opinions, or to defend his practice, or to enforce his stipend: all such matters are referred to the bishops or other ecclesiastical authorities, and are withdrawn almost entirely from the jurisdiction of the ordinary law-courts. The costs of solicitors, again, are never taxed by a jury, but by officers appointed by the judges; and as for attorney's charges, there is a certain fixed and invariable tariff, to which the public must submit, even if individual ruin should be the consequence. But, in the case of Medical men suing for their accounts, it is practically left to the jury to decide upon the reasonableness or otherwise of the charges made, and even sometimes upon the propriety or impropriety of the treatment adopted. When our brethren are driven into Courts of Law, it is generally in consequence of some flagrant act of shabbiness perpetrated against them by their patients; and sometimes, we must admit, the law is invoked by a small section of our body as an instrument of oppression. The two cases to which we are about to refer, and of which we publish a report in our present number, will in some measure illustrate the remarks we have just made.

In the first case just decided in the Court of Common Pleas, *Harrison v. Grady*, the plaintiff, a Medical man, attended a lady who, during a part of the attendance, was separated from her husband, and in an action tried at Westminster, Mr. Harrison obtained a verdict, but an attempt was afterwards made to enter the verdict for the defendant on the ground that the latter had not given his wife authority to pledge his credit to the plaintiff. The case having been argued, the Lord Chief Justice delivered a very able judgment, confirming the verdict of the jury and supported his views on various technical grounds. After showing under what circumstances a wife might legitimately pledge her husband's credit, his Lordship stated that it was perfectly clear that Medical attendance would be a matter of primary necessity, and that if the husband was not liable in such a case, then no one was liable, and a Medical man must attend the patient without any prospect of remuneration. He therefore came to the conclusion that the verdict ought to stand, and in this view all the other judges concurred.

There can be no doubt that this decision was correct, and the plaintiff, it will be admitted, had no course left to him but to bring his case into a Court of Justice, or to be deprived of the amount due for his services. It would, indeed, be a great hardship to the Medical Profession generally if each of its members, when called upon to attend a married lady, were obliged to make himself acquainted with the terms on which she lived with her husband; or if a husband had the right, by quarrelling with his wife, or turning her out of doors, to repudiate any lawful demands made upon him for Medical attendance. The decision in the case is therefore important, and will no doubt form a precedent for guidance on future occasions.

In the other case, which occurred lately in the County Court of a town in Yorkshire, we cannot say that the plaintiff, also a Medical practitioner, appears before the public in a similarly advantageous light. It appears that this gentleman brought three actions on the same day against various persons for Medical attendance and medicines. The defence in each suit was that the plaintiff had volunteered his services, and had indeed pressed them upon the patients against the wishes of the friends and relatives, and it was moreover stated that all three cases had been pronounced by the plaintiff to be labouring under typhoid

fever. Whether the latter statement was true or not, it is of course impossible for us to determine, but it is stated by one of the witnesses in the first trial that the patient, when supposed to be labouring under this malady, not only scrubbed the floor of her house, but brought in from the fields upon her back a five-bushel sack of potatoes. In the second case, if the evidence is truly reported, the line of conduct pursued by the plaintiff was even more questionable in point of taste and propriety. The patient is said to have been attended by another practitioner when the plaintiff was called in, and it is added that the latter unnecessarily continued his attendance, and sent medicines which were never swallowed. The plaintiff, in his evidence, justified this conduct on his own part on the pretext that the other Medical gentleman was not only drunk when he was called in to the patient, but that he was habitually in that condition. The gentleman referred to, who was in court and was called as a witness, indignantly denied this charge, for which, we must add, there appears to be no real foundation.

In all three cases the verdict was for the respective defendants, and we cannot say that we find fault with the decision. It is no doubt difficult for a young man to acquire a practice and a position in life, perhaps, in the face of obstacles and opposition, but nevertheless, he will seldom succeed in his object by forcibly breaking the barrier which he ought to hope to see opened before him, by disdaining those rules of professional etiquette, the observance of which distinguishes our calling from many other pursuits in life.

But, while thus expressing our opinion upon the equivocal attitude assumed by the plaintiff in these trials, we must express our astonishment at the conduct of the presiding judge, which seems to us strangely inconsistent with the dignity of his position. In reference to some observation made by the plaintiff, the judge is reported to have said, "Hold your tongue, sir, *or I must call for one of your* [illegible] *pestles to put down your throat!*" and, again, on the production of one of the bottles of medicine said to have been supplied to, but not swallowed by, the patient, his Honour said, "Take the cork out of the bottle, *and hold it to the doctor's nose!*" and his Honour also bid the latter take the medicine if he liked, but added, "For your own sake, sir, dont take it; *if you want to poison yourself take it outside the court.*"

Medicine does not cut a very graceful figure in this Yorkshire case, we cannot say much for the demeanour exhibited by her sister, Law. The language reported to have been used by the judge is more like that of a browbeating Old Bailey lawyer, than of a gentleman presiding on the seat of justice.

MEDICAL PRIME MINISTER.—The Premier of Nova Scotia is Dr. Charles Tupper, a practising physician at Halifax.

MEDICAL CORONER.—At a meeting of the Mayor and Town Council of Thetford, held at the Town hall on the 15th inst., Dr. T. R. Mitchell, F.R.C.S.I., was appointed Coroner for the borough.

REVIEW OF BOOKS.

On Some of the Causes and Effects of Valvular Disease of the Heart: being the Croonian Lectures of the Royal College of Physicians for 1865. By Thomas B. Peacock, M.D., F.R.C.P., Physician to St. Thomas's Hospital, and to the Hospital for Diseases of the Chest, Victoria Park. Pp. 114. London: Churchill and Sons. 1865.

In this Course of Lectures Dr. Peacock draws attention to a class of cardiac diseases which has not been hitherto very generally studied in consequence of the greater care bestowed by practitioners on the results of inflammatory affections. The causes of valvular disease of the heart, or of defective action of these parts, are, according to Dr. Peacock, 1. Malformation leading to regurgitation, obstruction, or obstruction and regurgitation; 2. Injuries of arterial and auriculo-ventricular valves, either immediate or gradual, leading to regurgitation, with or without obstruction; 3. alterations in capacity of orifices and cavities, leading to regurgitation from erosion or mal-adjustment; and 4. Inflammatory affections, chiefly rheumatic, acute, and chronic, leading to obstruction or regurgitation, or both these conditions combined. Of these different causes of disease Dr. Peacock treats only of the first three, as he conceives that the fourth has been already fully illustrated by preceding writers and lecturers.

The malformation of the valves may be of different kinds, their number being sometimes in excess and sometimes defective: four or five semilunar aortic or pulmonary valves being sometimes met with, or the number being reduced to two, or the apparatus, consisting of a single imperfectly-formed curtain. These conditions Dr. Peacock conceives to be due to intra-uterine disease, although other explanations have been given. That kind of irregular development in which the valves are in excess, does not appear necessarily to interfere with their functions, but that in which one or more of the segments are blended together, is probably always a source of more or less obstruction, and often lays the foundation of serious disease. Dr. Peacock adduces eleven cases in illustration of these views, and he believes that malformation of the valves may be suspected during life when the signs and symptoms of uncomplicated aortic valvular disease manifest themselves in persons who have never had rheumatic fever or other serious illness, and who have never sustained any severe accident, or followed for a long period a laborious occupation. The inference will be strengthened if the patient is young, or has not attained middle age.

Another cause of valvular disease or defect is the reception of an injury, which may be immediate, one or more of the valves being torn, or may act more gradually, some portion of the apparatus yielding under long-continued straining or pressure. Of such occurrences Dr. Peacock adduces five examples, in which the valves were injured by some accidental circumstance, and he observes that he has seen several cases of incompetency of the aortic valves in the "along-shore men" who are employed to load and unload the small coasting vessels, and among coal-whippers, and the Newgate market and Deal porters who carry very heavy weights upon their shoulders, and often up slanting planks or landings, in which positions the stress upon the aortic valves must be excessive.

A third cause of valvular defect consists in alterations in the capacity of the orifices and cavities of the heart, which may arise from inflammatory disease affecting the valves themselves, or from changes in the condition of the adjacent cavities and vessels, preventing their being properly adjusted so as completely to close the apertures. Dr. Peacock omits the consideration of the former as inconsistent with his plan, and he adduces eight cases illustrating maladjustment of the valves, dilatation of the left auriculo-ventricular aperture, and alteration in the capacity of the aortic orifice.

In the third and last lecture, Dr. Peacock treats of some of the effects of disease of the heart upon the weight and dimensions of the organ itself; and in order to estimate the nature of these changes more correctly, he prefaces his

remarks by a notice of the weight and size of the healthy organ. To ascertain these particulars is by no means easy, because even in the limits of health there are several variations, and these variations are much increased in disease, even when cardiac disease is excluded. Tables are accordingly given by Dr. Peacock, showing the average weight of the healthy heart, and in acute and chronic diseases, and at different ages in males and females, and also the dimentions of the healthy heart in males and females; there are also tables of the weight and dimensions of the heart in different diseases, and when it is diseased itself. These observations as to the condition of the heart, whether healthy or diseased, are, of course, closely related to the investigations of several important pathological questions, and are also of great interest in a practical point of view. Dr. Peacock concludes his lectures by pointing out the various conditions and symptoms which are characteristic of each form of valvular disease, and he briefly alludes to the treatment which ought to be adopted in such cases; recommending generally the employment of alcoholic stimulants in organic disease of the heart, and advising a cautious employment of digitalis.

Dr. Peacock's lectures contain, as will be seen from the above brief notice, a great mass of important matter relating to valvular disease of the heart, and they are the more valuable because they comprise the elucidation of subjects not generally treated in works on cardiac pathology.

Lectures, chiefly Clinical. By Thomas King Chambers, M.D., Honorary Physician to H.R.H. the Prince of Wales, Consulting Physician and Lecturer on the Practice of Medicine at St. Mary's Hospital, Consulting Physician to the Lock Hospital. Fourth Edition. Pp. 612. London: Churchill and Sons.

The simple fact that a purely Medical work, of the size and price of this volume, has, in a very few years, reached its fourth edition, the last edition having been exhausted in considerably less than two years, affords conclusive evidence that it must be a book of no ordinary merit. Most of our readers are doubtless aware that about a year and a half ago Dr. Chambers was obliged to submit to a very serious surgical operation; and as, in the time of his severe trial, he had the sympathy of all his Medical brethren,—whether they knew him personally or only through his writings—so now, to use his own words, "on his return, by God's grace, to health and labour," he has our hearty congratulations. As the earlier editions of these lectures were noticed at some length in the pages of this Journal, we shall merely extract six hexameter lines which give a capital description of the normal order of phenomena in a case of small-pox.

"Bis sex celatur virus, tres febre notatur,
Fertque duos soles papulam, tres postea opaquam
Vesicam, roseumque duos perfectior orbem;
Vincla cutis medii dissolvit postera luna.
Bidua vultum onflat vesica, movetque salivam.
Pustula fert distenta narûmque pedumque tumoren."

P. 118.

This volume deserves to find an honoured place in every physician's library, side by side with the corresponding books of Graves and Trousseau.

Transactions of the Pathological Society of London. Vol. XVI. London. 1865.

The Pathological Society, as is well known, is one of the most flourishing Medical Societies in this metropolis, and this distinction is in great measure owing to the practical nature of its proceedings and to the exhibition of the numerous morbid structures presented at the periodical meetings. Another and no less important feature is the annual publication of a volume of Transactions, recording the history of each of the specimens exhibited, and, where it is practicable, perpetuating the appearances they present by the illustration afforded by well executed engravings. In this volume, as usual, the objects are arranged according to the pathological category to which each belongs, and there are twelve plates, and twenty-four woodcuts. Those who have attended the meetings during the past year, or those who have followed the course of the proceedings by means of the reports published in our own and other journals, will be aware that the transactions were of more than average interest, and in the present published volume, they are all recorded in a systematic form, forming another valuable collection of pathological facts, the collection and arrangement of which reflect the highest credit upon the indefatigable secretaries of the Society, Dr. Murchison and Mr. Holmes.

On the Treatment of Enlarged Tonsils at any Period of Life without the Operation of Excision. By William J. Smith, M.B. London, Surgeon to the Islington Dispensary. Pp. 55. London: Hardwicke. 1865.

The title of this little work is calculated to mislead patients, because it seems to imply that the operation of excision is inexpedient, and that it has been successfully replaced by some other plan devised by the author. This however, is not the case, for he expressly states that the operation is not only unattended with danger, but he points out numerous conditions in which these organs ought to be partly or wholly removed. Still there are instances where the patients do not choose to submit to the operation, and the proceeding is impracticable in young children. Mr. Smith therefore tried successively cauterisation by blisters and iodine at the angles of the jaw, and the application of nitrate of silver to the tonsils, but without effect; and at last he adopted cauterisation by potassa fusa, and he states that he has found the plan successful. He has also invented an instrument for the convenient application of the caustic potash. Mr. Smith admits that excision is a far more speedy operation than cauterisation, but he recommends the latter in cases where excision is impracticable or is objected to. Viewed in this light cauterisation may perhaps be allowable, but the candid tone adopted in the book itself does not correspond with the announcement on the title-page, which seems indirectly to condemn the operation of excision and thus to court the suffrages of the timid.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. T. K. CHAMBERS concludes his course of three lectures "On the Effects of the Climate of Italy." He now points out in order, under the several seasons, the classes of patients to whom an Italian atmosphere is curative. The common feature in all the cases enumerated by Dr. Chambers as likely to profit by an Italian climate, is a weakness of circulation and consequent tendency to chronic and degenerative changes. But some morbid states of body are made worse by a residence in Italy; for instance, all cases of apoplectic habit and of congestive inflammation, and early cases of tubercular consumption with a quick excitable circulation, and a liability to hæmoptysis. Piles and menorrhagia are made worse, and are sometimes brought on, by travelling in Italy. Dr. Chambers concludes with some practical hints for the guidance of persons who propose to try the sanitary effects of an Italian climate. Among the recommendations he gives, are that the patient should be as much in the air as possible, should avoid changes of temperature, should drink light wine, and should adopt, as far as he can, the diet of the people. Patients also should not remain too much in one spot, nor, on the other hand, should they travel too rapidly from one place to another, thus, in fact, passing the greater part of their time in a close travelling carriage or a railway car.——Mr. JOHN GAY contributes a paper "On Stricture of the Œsophagus," and relates two cases of that affection which fell under his notice. The first was that of a lad, nine years old, who

swallowed by mistake some sulphuric acid and subsentlly had a stricture of the œsophagus, to such an extent o threaten starvation. The method of treatment adopted dilatation, and after some time, and much difficulty, an intercurrent attack of congestion of the upper lobe he right lung, the stricture was cured. The other case that of a female, aged fifty, in whom the disease pre-ed itself without any known cause. After six weeks' mpt at dilatation the point of the instrument passed ough, and Mr. Gay believes that it went in the right di-ion, but the proceeding gave her very great pain, and sunk and died in a few days. No post-mortem examion was allowed. Although the second case was an uccessful one, Mr. Gay believes that an attempt at tation should be made in the cases of stricture of the phagus, unless the disease should be malignant, in which the operation would be, of course, worse than useless. ides the malignant forms, Mr. Gay divides these stric-s into the traumatic and the idiopathic, and it is in the ner that dilatation is most easily performed, and is most uently successful.——Dr. HORACE DOBELL concludes paper "On the Assimilation of Fat in Consumption," adduces some additional evidence of the value of his reatic emulsion in the treatment of consumption.——GEORGE BUCHANAN, of Glasgow, in continuing his s of clinical surgical cases, relates "A Case of Fracture he Spine." The patient had fallen from a ladder at a iderable height, and he fell with his feet foremost. The ptoms during life were very obscure, and injury to the ulla was only inferred as probable. No fracture could etected on careful examination, and the injury was sup-l at first to be unimportant. But the patient suffered wards from diarrhœa, retention of urine, and other symptoms, under which he sunk, and after death it was id that the twelfth dorsal vertebra was fractured trans-ely, and there was an abscess around it.

THE 'MEDICAL TIMES AND GAZETTE.'

. BENCE JONES continues his lectures "On Local nical Disorders arising from Suboxidation, and their anical Results," and he now shows that the local of cold upon the living textures is, in fact, a process oxidation. The general effect of cold is to stop cal action, and this gives rise, secondly, to the nical stoppage of the circulation of the blood. Mor-ion of the extremities, frost-bite, and chilblains are, ing to this view, local effects of suboxidation. er illustration of local suboxidation is fatty degene-and a table of fatty acids is given, showing that re a multitude of fatty substances, each containing gen than that which precedes it. Fatty degenera-herefore, may be considered a disease of suboxida-he amount of degeneration depending upon the sive diminution of oxygen in the textures.——Dr. HARLEY continues his lectures "On the Urine and s of the Urinary Organs," and he now treats of dia-ellitus and its rational treatment. Although this is very intractable, and many vaunted remedies have out to be worthless, yet medicine is often of great and more especially that branch of it which relates There are two great types of diabetes—namely, to excessive formation, and that due to diminished tion, and each requires a different mode of treatment. On the subject of treatment of these forms, we quote Dr. Harley's own words :—

"Even in the most favourable cases for restricted diet we must never allow ourselves to be deluded into the idea that, because we are mitigating the symptoms, and reducing the amount of sugar in the urine, we are necessarily curing the disease, or we shall frequently be doomed to sad disappointment. In keeping a patient on restricted diet, we are merely withholding from him the straw and mortar out of which the bricks are made,—not removing the makers—so that, as soon as the straw and mortar is refurnished to them they will again be found at work as actively as ever. It is true that it occasionally happens during the withdrawal of the straw and mortar the makers disappear; but this, unfortunately, is by no means invariably or even frequently the case ; it is rather, indeed, the exception than the rule. We must therefore rely on other means for the removal of the makers. Of these other means I shall presently speak. Meanwhile, let me explain that by the term restricted diet, we mean not only the avoidance of all sugars, and substances containing saccharine matter, but also of all kinds of food convertible during the process of digestion into sugar. The foods convertible into sugar in the digestive canal are those containing starch (not gums), such as arrowroot, tapioca, sago, flours of all the different kinds of cereals (wheat, barley, oats, peas, beans, &c.), potatoes, carrots, beetroot, parsnips, turnips, and other edible roots.

"Green vegetables, on the other hand, such as spinach, cabbage, turnip tops, Brussels sprouts, and lettuce need not be forbidden, as they contain too small an amount of starch to do much injury.

"As for animal foods, on the other hand, every imaginable kind of fish, flesh, and fowl may be indulged in, so that even on the most restricted diet the patient has still a large margin for selection—beef, mutton, pork, venison, poultry, game, and wild fowl, oysters, lobster, crabs, prawns, salmon, cod, turbot, &c., Iceland and Irish moss, calf's foot or gelatine jellies, butter sauces, and salad oils. The only true hardship, in fact, the patient suffers is the deprivation of ordinary bread, and that appears to be a more severe one than most people imagine. I have known patients in whom the craving became at last almost intolerable, as if nature were crying out for some indispensable element of food. In order to mitigate this hardship, a great number of plans of depriving bread of the forbidden element, starch, have been suggested, and many of them have been in a great measure successful. Thus, we have bran, gluten, almond, and glycerine breads and biscuits constantly kept in stock by many of our London bakers.

"After a time patients get very tired of these substitutes, so it is as well to know that we may occasionally indulge them with well done toast, or very crisp pulled bread, the extra heat having destroyed a considerable portion of the starch normally contained in the article.

"As regards drinks, all such as contain saccharine matter are to be avoided ; such, for example, as sweet sparkling wines, whether they be champagnes, moselles, or hocks. An embargo is also to be put on all liqeuers and fruity wines, such as young port, Roussillon, &c. ; sweet ales, stout, and porter are also to be shunned. If the patient is to be indulged in wines at all, let him have dry Lisbon, old Madeira, Manzanilla, or Amontillado sherries, Chablis, Niersteiner, or old Sauterne ; sound clarets may also be indulged in. When stimulants are deemed requisite, brandy, whisky, rum, or Hollands may be used ; but these ought always to be employed with caution for the reasons previously given, when speaking of the artificial production of diabetes by means of stimulants introduced into the portal circulation.

"All that has now been said regarding regimen has of course only had reference to that form of diabetes arising from *excessive formation*. There are no restrictions either as regards food or drink requisite in cases springing from *defective assimilation*. On the contrary, the duty of the Practitioner is to select for his patient not only that which is most nourishing, but also that most easy of assimilation. He will often find, too, that such cases not only tolerate but

even demand the free use of stimulants, in order to support the flagging vital energies, and enable the weakened organs to perform their work. I think if I were asked what is the best remedy for diabetes, I might venture to answer, in the language of Opie, when the student inquired what he mixed his colours with, 'BRAINS, SIR.' For to say that any one remedy or particular line of treatment is suitable to all cases of diabetes would be simply charlatanism of the worst sort.

"For example, when diabetes arises from a traumatic lesion of the nervous system, it is not the symptom of saccharine urine that we treat. It, we know, will disappear when the nerve-lesion is healed. All our energies are, therefore, directed to the hastening of the healing process.

"On the other hand, when the cause is not traumatic lesion, but disease of the nervous system, which we know is neither likely to disappear of itself nor by treatment—such, for example, as tumour of the pneumo-gastric nerve—our efforts are directed to the subduing of its effects."

——Dr. E. LEVIER, of Florence, communicates a "Case of Apoplexy into the Spinal Cord." The patient was a girl who, at the menstrual period, was attacked with pain in the sacro-lumbar region, followed by paraplegia, retention of urine, and involuntary fæcal evacuations. She lingered for about two months, and then died; and on post-mortem examination, it was found that in the spinal cord, from the tenth dorsal vertebra downwards, there was grey softening, with a hæmorrhagic centre.——Dr. JOHN PATTERSON, of the Egyptian Medical Service, contributes a paper "On the Late Pestilence in Cairo." The writer gives a short account of the invasion of the disease, and then describes its features as he observed it in practice. He states that premonitory diarrhœa was not a distinctive character of the malady, for the majority of the cases showed no such symptom, the patients being suddenly struck down in the prime of life and in good health. Numerous remedies were employed, but Dr. Patterson does not speak with confidence of any of them, and some of the measures adopted, he thinks, did more harm than good. He believes that the seat of the disease is the sympathetic system of nerves, which is paralysed, and alters the functions of secretion and absorption.

OBITUARY.

MR. EDWARD TEGART.

A common street accident has deprived the Profession of one of its most estimable members, and society in general of a warm-hearted and genial friend.

On Friday, the 10th inst., Mr. Tegart had left his club in Pall mall about six, in perfect health and spirits, to walk home, but on crossing St. James's street, near Piccadilly, he was knocked down by a Hansom cab. He was picked up by a policeman who witnessed the injury, and taken to St. George's Hospital, where he was well known from being one of the Committee of Governors and also holding an honorary Medical office. He was perfectly insensible, with a contused wound over the right temple, and rigid paralysis of the right arm. He recovered consciousness for a short time that evening, but the next day became delirious and prostrate. An erysipelatous swelling of the wound supervened, and he sank on Tuesday week. Some doubt existed at first whether he had been knocked down or had fallen in a fit. The post-mortem examination, however, which revealed a fracture of the frontal bone on the right side, and effusion on both sides of the brain, makes it certain that he was the victim of the accident.

Mr. Tegart was born towards the end of the last century, and was in his seventieth year. He was of Irish extraction, and his father, who came from the North of Ireland, served his apprenticeship to the father of the present Mr. N. B. Ward, F.R.S. When his time of service had expired, Mr. Tegart, the father, took up his residence in the West End of London, and practised most successfully as an Apothecary in Pall mall. He moved in some of the best circles of society, being especially patronised by the Roman Catholic nobility and gentry, he and his family being attached to that form of religious faith. But although he enjoyed an excellent practice, he left no fortune at his death, and, indeed, he left his estate somewhat encumbered; and although his son succeeded to the business, he was obliged to clear away many of his father's responsibilities before he began to reap any benefit for himself. The business, however, was a particularly good one, and Mr. Edward Tegart had no great difficulty in clearing off old scores, and securing an excellent and lucrative practice, his success being further enhanced by fortunate events connected with his domestic history. After practising for a long time in Pall mall, until his house of business was destroyed for the construction of the Army and Navy Club, he removed to Dover street, Piccadilly, and there he remained until about four or five years ago, when he suffered from an attack of paralysis, which, however, left no more serious result than a certain thickness or embarrassment of speech. But now he retired from the more active duties of the Profession, and after residing for some time in Paris, he returned to London, and settled in Onslow square, occasionally rejoining his friends in social circles, and to a limited extent engaging in practice among some of his old patients. One of his last patients was Cardinal Wiseman, with whom he was intimately acquainted, and whose funeral he attended in the early part of the present year.

Mr. Tegart was an "Apothecary" *pur et simple*, and he prided himself upon the distinction. He belonged to that class of practitioners now fast dwindling away, who maintained the old distinction of physicians, surgeons, and apothecaries, and he boasted of belonging exclusively to the last category. But because he was a member of this division of the Profession, he was very far from being either an ignorant or an illiterate person. He was in fact an accomplished gentleman, a very fair scholar, an able and judicious practitioner, and a man of considerable, if not profound, scientific attainments. His manners were polished and elegant, his appearance was aristocratic, and his demeanour uniformly courteous and conciliatory. He never contributed to Medical literature, being probably too much engaged in active practice to be able to do so, and his leisure time being spent in society, of which he was a very genial member.

He was long a member of the Court of Examiners of the Society of Apothecaries, and for several years was Chairman of the Court. In all the measures taken by that body for the improvement of the education of the general practitioner, he took the warmest interest, and was among the foremost in carrying out the Regulations securing a Preliminary Examination in Arts; a measure first started by the Society of Apothecaries and enforced by them in the case of their own licentiates, and now adopted by the Medical Council for all members of the Profession. At the close of his connexion with the Court of Examiners, it was generally hoped that he would be elected as the first representative of the Society of Apothecaries in the General Council of Medical Education, a post for which he was peculiarly well-suited by his thorough acquaintance with the educational progress of the Society, and his non-election caused no less surprise than disappointment.

By his colleagues Mr. Tegart was loved like a brother, and on his retirement from the Chairmanship of the Court of Examiners, a handsome service of plate was presented to him by that Court, in testimony of his unvarying urbanity, his assiduous attention to his duties, his kind and conciliatory manners, and his splendid hospitality. Of the Monday Club, as it was and is called, consisting of some of the most distinguished practitioners of all grades of the Profession, he was many years President, and his retirement from it on the occasion of his paralytic attack was the cause of universal regret.

Many a social circle was enlivened by his humour, which

was "wont to set the table in a roar," and it was hoped that his life might yet have been spared for many years to come. But "in the midst of life we are in death," and on Tuesday week his card was on the table where many of his old colleagues and friends were expecting to meet him at dinner, but his seat was vacant, and the whisper went round the board that poor Tegart was no more!

LEGAL INTELLIGENCE.

COURT OF COMMON PLEAS, Westminster, Nov. 14.
(Sittings in Banco.)

HARRISON v. GRADY.

This was an action tried at Westminster before Mr. Justice Byles, when a verdict was found for the plaintiff for the amount of his bill for Medical attendance. A rule *nisi* having been obtained, pursuant to leave reserved, to move to enter the verdict for the defendant, on the ground that the learned Judge ought to have left to the jury the question whether the defendant had given his wife authority in fact to pledge his credit to the plaintiff, to-day the rule came on for argument.

The plaintiff it appeared is a Medical man who had been called in by the defendant's wife to attend her from 1860 to 1864, while she was cohabiting with her husband, and subsequently after she had separated from her husband, she having a separate estate. The defendant relied on notice to the plaintiff, while his wife lived with him, that she had no separate estate out of which his bill was to be paid. The plaintiff relied on the legal presumption that the defendant's wife, while cohabiting with him, was presumed to be his agent to pledge his credit, and that, after his wife had separated from him while in a bad state of health, medical attendance was a necessary thing, for which he was liable.

The Lord Chief Justice, in giving judgment, said he thought the rule ought to be discharged. The action was brought by the plaintiff, a Medical man, against the husband of the lady to whom the Medical attendance was given, and the question was whether the wife had the authority of her husband as agent of her husband to make him liable for such attendance. The authority of the wife might be *presumptio juris*, unable to be rebutted, as, where the wife was turned out of her home without any supply of necessaries, there a presumption of law arose that she was turned out with authority to pledge her husband's credit for necessaries, and he was of opinion that an extreme case of ill health made Medical attendance a necessary; as the husband in this case had turned his wife out in 1864 while in ill health and the plaintiff had supplied her with Medical attendance after that time for 7*l.*, the amount of that attendance, the verdict must stand. Between 1862 and 1864 the question was whether the defendant's wife had authority, as the agent of her husband, to make him liable for Medical attendance supplied by the plaintiff during that time. That question depended on presumption of fact. The case of the plaintiff as launched was that the defendant's wife was cohabiting with her husband, and it was a presumption of fact from cohabitation that the wife was the agent of the husband for getting supplies for carrying on their domestic establishment. The consideration whether the thing supplied was necessary for the state and degree of the husband led to confusion. The jury are to consider whether the goods supplied are suitable to the station which the husband authorized his wife to assume. Where the wife was living with the husband it was a presumption of fact that she was the agent of the husband for ordering the goods ordered by her to be sent into the establishment. If the goods were unsuited to her station, a presumption arose on the other side that she was not the husband's agent to pledge his credit for them; as if a day labourer should go to a jeweller's shop and order a diamond ring, the presumption was that the husband never gave authority to his wife to order what was unsuitable to her station and degree. But, as a general principle, the presumption was that the wife was the agent for the husband to order the articles which she ordered to be sent to their establishment. He attached extreme importance to the judgment in the case of "Jolly *v.* Reece," on the ground that that judgment maintained the right of the husband to determine what was the degree that his family should live in and what station they should hold. Whatever the husband chose to fix as the standard of living for his family he had the right to do; and no tradesman supplying goods without the authority of the husband should be allowed to set up a standard of living for him, for which the goods might be supposed to be suitable, different from the standard of living set up by the husband. That standard of living set up by the husband was the standard that the jury would consider if the question came before them. If that were not the law, it would leave every demand of this kind a question of degree and of fixing the standard on which a man might wish his family to live to the judgment of a jury, as to what they thought he ought to afford. It would mischievously expose the sources of income, and lead the wives of industrious men compelled by their avocations to be away from home to be imposed upon by tradesmen in the sale of goods to them supposed by the tradesmen to be within their husband's means, which the husband would have to pay for. If that point was to be considered at all, it was perfectly clear that Medical attendance would be one of the most primary necessity. The question as to this part of the case was a presumption of agency in the wife from cohabitation. But the defendant said, "You had notice that my wife had not my authority to pledge my credit;" and he relied on two conversations with the plaintiff as to that fact. He (the learned Judge) thought, as a juryman, that those two conversations did not rebut the presumption arising from cohabitation. If the husband was not liable, the plaintiff was supplying his Medical attendance without any one to be liable for it. He supplied Medical attendance to the wife with the knowledge of the husband, and sent in his bill in the name of the husband. He had, therefore, come to the conclusion as a juryman, with respect to the part of the plaintiff's claim, that the verdict ought to stand.

The other learned judges were of the same opinion.—Rule discharged.

STOKESLEY COUNTY COURT, YORKSHIRE.
Friday, Oct. 20th, 1865.
(Before Mr. Sergeant Dowling, Judge.)

SANDERSON *v.* MEDCALF.

This was a claim for Medical treatment of a daughter of the defendant. The said daughter was engaged to a Mr. Storey, a farmer, and was suddenly taken ill—the principal symptom being prolonged constipation. Mr. and Mrs. Storey accordingly called at the shop of a chemist who was brother to plaintiff. The chemist was asked for some castor oil, but instead of supplying it he called his brother, who said it would be better if he were to see the girl. To this Mr. and Mrs. Story objected, but plaintiff said that he would not charge them anything; upon which he was allowed to call and see the girl, according to his wish. When Mr. Sanderson reached the house, Miss Medcalf had gone to bed. Upon seeing the patient, Mr. Sanderson said that she was suffering from a disease bordering on typhoid fever, and that he would send up some medicine immediately. Mr. Storey accordingly called for a powder, which was to be given to the girl, and if she were not relieved, Mr. Sanderson would call again in the morning. In the morning, according to Mr. Storey, plaintiff changed his tone, and said it was decidedly a case of scarlet fever. Plaintiff then ordered the girl to remain in bed, and, without any further instructions, continued to call and leave the medicine. For this medicine and attendance the plaintiff charged, and was, by this action, endeavouring to recover. Mr. Sanderson asserting that Mr. Medcalf had called upon him and told him to do the best he could for the girl. This Mr. Medcalf denied, and called Mr. Storey and the whilom patient, from whose evidence it appeared that the the medicine supplied by plaintiff made his patient so much worse that it had not all been taken, and the girl was cured by a dose of castor oil administered by Mrs. Storey. Mr. Storey said the

medicine given by plaintiff was expressly given to relieve the bowels; and, he continued, "it neither did so then nor has it done so since."—His Honour: How long ago is this?—Mr. Storey: Two years.—His Honour: And do you mean to tell me that that poor girl's inside has been in that state ever since? (Loud laughter.)—Mr. Storey: No, sir; but it was the castor oil. Mr. Sanderson told me that the girl was in a dangerous state; and yet she got up that morning and scrubbed out the entry, after which she went and fetched in from the field a five-bushel sack of potatoes on her back.—Mr. Sanderson: I say from my Professional knowledge that it was unsafe for the girl to get up when she did—absolutely dangerous.—His Honour: Manifestly so. She was suffering from fever, and we all know that persons suffering from fever have at times accessions of unnatural strength. It seems to me, Mr. Sanderson, that you offered to see the girl without charge, by way of introducing the thin end of the wedge, in the hope that you might introduce any amount of timber subsequently. Verdict for the defendant.

SANDERSON *v.* BLACKLOCK.

A BILL FOR MEDICAL ATTENDANCE.—Mr. Griffin, for the defence, said that the defendant belonged to a club at Brotton, of which Dr. Collins is the surgeon. When defendant was ill, Sanderson was called in to attend him in the absence of Dr. Collins. He visited defendant in the morning and in the evening. Dr. Collins called, and from that time regularly attended Mr. Blacklock. Mr. Sanderson was told on the 26th that his services were not required, but he continued to call from time to time and leave medicine: 10s. had been paid into court.—Mr. Sanderson: Defendant is in the employ of Mr. Ritson, and was ill with typhoid fever.—His Honour: Typhoid fever, again? Mr. Sanderson: Yes Sir. He told me at the time I was called in that his doctor was incapable and drunk. He was forced to have me.—His Honour: Perhaps that might be the only reason for his taking you? (A laugh.)—Mr. Sanderson (cross-examined): I first attended on the 25th July; on the 26th he told me that he was getting on very well. He never told me that he should not require my services any longer. When I made my claim he said it would be paid at the works and be stopped from Dr. Collin's salary.—Mr. Blacklock said: On the 25th I was attended by Mr. Sanderson and also by Dr. Collins on the same night. On the 26th, Mr. Sanderson called again and I told him that I had seen my own doctor, and that if I wanted him (Mr. S.) again I would send for him. Dr. Collins attended me regularly from the 25th until I got well—Mr. Sanderson: That is all.—His Honour: If you don't hold your tongue, I must call for one of your own pestle's to put down your throat.—Mr. Blacklock then produced the medicine which Mr. Sanderson had left at his house unasked. There were two small bottles—a large black one (apparently once in use for wine)—and a powder.—Mr. Sanderson denied that the medicine was that he had supplied.—His Honour: What is in the black bottle? Let him (Mr. S.) taste it, if he likes. But, for your own sake, sir, don't take it. If you want to poison yourself take it outside the court.—Mr. Sanderson: He must have taken my medicines because Dr. Collins was drunk all the week. The defendant's statements are false throughout.—His Honour: Are those bottles yours? (To defendant.) Take the cork out of the big black bottle, and hold it to the doctor's nose.—Defendant: Dr. Collins is here your Honour.—His Honour: Then let him be called; we have heard a great many statements against his character, it is only right that he should be heard.—Dr. Collins: I treated the defendant from the 25th of July until he recovered, and supplied him with everything necessary.—His Honour: The plaintiff says you were drunk, is that true?—Dr. Collins: If I was drunk then, I am now. I have not such a pale face as he has—I am always flushed—so he represents me as drunk. The last time that he called at defendant's house, he said, "I am going to preach at the Wesleyan Chapel, Skelton, and I will leave these bottles." The fact is, your Honour, he is always doing this, and uses the Methodist pulpit as a cloak.—Mr. Sanderson: Mr. Collins will say anything. He is nearly always drunk. You can see him so in the street.—His Honour: Will you, Dr. Collins, smell at that big bottle.—Dr. Collins: I have nothing to do with that, sir.—His Honour: That is a most extraordinary black bottle; neither of these gentlemen will put his nose to it. Why should you be ashamed of your own offspring.—Mr. Sanderson: You look at it with a degree of dislike unbecoming a parent.—Judgment for the defendant.—An officer of the Court, at the conclusion of the case, removed the bottles when his Honour instructed him to take care; while doctors were afraid of them, it was quite right for an officer of the Court to take care of them.

SANDERSON *v.* GEO. PEACOCK.

This was a claim for Medical attendance of one of Mr. Peacock's children, who was suffering from typhoid fever.—His Honour: What! typhoid again?—Mr. Sanderson: Yes, sir; and a very severe case.—Defendant: The facts are these, sir. I rode down on my son's pony to the chemist's shop kept by Mr. Sanderson's brother. I wanted a dose of castor oil or something else. Mr. Sanderson volunteered to go back with me, as he said he wanted people to see he had a practice, and "initiate" himself into the favour of the well-off people by showing what he could do. When he saw the boy he said that it was the measles, and that he would send a little medicine up. He came again and gave me a powder to put in a bottle of water from the beck, and if we had not desisted from giving it to the boy he would have had to go before Mr. Sowerby. We gave the boy some castor oil and that cured him.—His Honour: In fact, the boy had the belly ache.—Defendant: Yes, sir; but I can't say what was the matter with the boy.—Plaintiff: My charge is only for medicine which comes to 1*l.* 4s. 6d. Had I charged for attendance I should have charged at least 3*l.* more as he lives at the Incline—seven miles off—and I had six journeys there.—Defendant: He sent me in a bill of six shillings, your Honour; and when I sent the money he refused it, saying it was the wrong bill. Do you think, your Honour, if I had owed him the money he would not have kept the six shillings while he could?—His Honour: Let me look at your book, Mr. Sanderson. His Honour, after looking at the book, said: You have told me an untruth Mr. Sanderson, you said that your charge was for medicine only, and, according to your book, it is for attendance, and I——Mr. S.: But if I had ——His Honour: Remember, sir, you cannot knock down a judge so easily as you can kill a patient.—Mr. S.: It is not my vocation to kill a patient.—His Honour: Silence, sir. You assume a style of flippancy ill becoming to a professional man. You told me distinctly that you had made no charge for attendance—only for medicine—yet in your book I find entries, *iter, iter, iter, vocator.* You see you have made a charge for attendance. What do you mean by *vocator?*—Plaintiff: Called out of bed early in the morning, sir.—His Honour: You have entered *iter*, 3s.; *iter*, 3s.; *iter*, 3s.; *iter*, 3s. 6d.; *iter*, 3s.; *iter* and medicine, 1s. It is quite evident you have again been trying the thin end of the wedge. Verdict for the defendant; half-a-crown to be allowed for medicine.—Mr. Sanderson: It is disgraceful altogether!

MEYER-BERCK FLESH-EXTRACT SYRUP.

Messrs. Newberry and Sons, of St. Paul's Churchyard, have just introduced into this country an article which appears likely to serve as a substitute for Liebig's Extractum Carnis, which is obtained with some difficulty, and consequently fetches a high price. Meyer-Berck's Flesh-Extract syrup contains, in one hundred parts, according to the report of Dr. Goutier, St. Martin, of Paris, forty parts of water, forty of sugar, and twenty of albumen-creatin and salts, and, according to the more accurate analysis of Dr. Julius Löwe, a chemist in Frankfort, the salts consists of chloride of sodium, sulphate of soda, phosphate of potash, phosphate of soda, phosphate of lime, sulphate of lime, and carbonate of lime. It is strongly recommended in the case of children suffering from imperfect nutrition, atrophy, and struma; in convalescence after eruptive and other fevers, where ordinary dietetic remedies are unsuccessful; in chronic catarrh of the stomach,

with loss of appetite and emaciation; in all conditions of anæmia and leukœmia, in scorbutic diseases, and after childbirth, and in sea-sickness it is said to rest well upon the stomach, and to renew the appetite. The dose is half a teaspoonful for very young children, a teaspoonful for those who are rather older, and two teaspoonfuls for adults, to be given every morning fasting and afterwards two or three hours before or after meals.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 14th inst.:—James Edward Adams, Finsbury circus; Edward Joseph Barry, M.D. Edin., Ramsgate; Henry Martin Body, Cheriton, North Devon; Edward Forster Brockman, L.R.C.P., Brunswick gardens, Kensington; Hamilton De Fatham, Dorset square; Charles John Stokes Digges, Dublin; Edward Mills Grace, Downend, Bristol; Andrew Christopher Jackson, Cape Town; John Bedford Kesswill, St. Germans, Cornwall; William John Land, Exeter; Charles Gray Montgomery Lewis, Sedgley; Francis Henry Lovell, Aspley, Woburn; John Shirley Steele Perkins, Exeter; Frederick Tickell Prince, Lawston, Cambridgeshire; Reginald Palgrave Simpson, Norwich; Charles Smith, M.B. Lond. and L.R.C.P., Basingstoke; Theodore Thomas Taylor, Tricklade, North Wilts; William Thomas, L.S.A., Birmingham; Alfred Walker, Albion road, Stoke Newington; Frederick Henry Ward, L.S.A., Scarborough; Edward Francis Willoughby, Bristol; Robert Good, L.S.A., Uttoxeter, Staffordshire.

The following gentlemen were admitted Members on the 5th inst.:—Frederick Lyndon Attwood, Marylebone road; John Attygalle, Calcutta; John Augustus Ball, Stradbrook, Suffolk; Robert Barker, Sunderland; Frederic Mainzer Charles Beechey, Wokingham; Robert Brennan, Croydon; Frederick John Burge, jun., L.R.C.P., Hammersmith; Henry Parry Chandler, Berners street; Thomas Cuddeford, Plymouth; Alfred John Freeman, Southsea; John Murray Gibbs, Sidmouth, Devon; Eustace Greenaway, Woodford, Essex; James D'Arcy Harvey, St. Just, Cornwall; Henry Hyde, Lamb's Conduit street; Albert Kisch, Circus place, E.C.; Alfred Swaine Lethbridge, M.B. Aberd., Musbury, Devon; John Murray Moore, M.B. Edin., Liverpool; Richard Plowman, L.R.C.P., Coleshill, Warwickshire; John Raby, L.R.C.P., & L.R.C.S. Edin., St. Germans, Cornwall; Samuel Sanders Stephens, Taunton; Henry Stubbs, L.S.A.; Stourbridge; John Hancocke Wathen, Fishguard, Pembrokeshire.

At a meeting of the Council on the 9th inst., the following gentlemen were elected Fellows of the College, their diplomas bearing date respectively Oct. 31st, 1834, and Aug. 4th, 1840:—Richard Rickman Shillitoe (Dep. Coroner for North Herts), Hitchin, Herts; Francis Ayerst Young, Hawkhurst, Cranbrook, Kent.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 9th inst.:—William Bell, Torrington square; William King, Moreton Terrace, Pimlico; David Thomas, Carmarthen; Edward Russell Woodford, Ventnor, Isle of Wight.

LIFE AND DEATH AT THE EAST OF LONDON.—On Saturday week, Mr. Humphreys held an inquiry in Bethnal-green, with respect to the death of a child, supposed to have died of fever caused by the pestilential locality while under the Medical charge of a person practising as a surgeon, but who held no diploma whatever, and the proceedings disclosed a deplorable feature of East-end life. Elizabeth Ann Mayhew, the mother of the deceased, stated that she was the wife of a wood-chopper. The child, who was six years old, had been ailing for three weeks previous to the 5th inst. when it died, and soon after it was taken ill she went to a Mr. Newby, whom she understood to be a properly qualified Medical man, and he attended. He sent the child bottles of "stuff," and it appeared to be getting over the disease (small-pox), but had the "doctor" said, a deal of fever. He said the child was getting on all right, but it gradually sank and died. The house in which the deceased died was a "two-roomed" one, one room above the other, and this was occupied by the family, eight in number. In the upper room slept witness, her husband, and four of the family, the eldest of whom was a daughter, twenty-one years of age, and in the lower room, which was below the level of the street, slept the two boys of the family. In the day the young children were kept in the kitchen, as witness had to be out at work all day. In cross-examination by the Coroner the witness said the roof of the top room was out of order, and the wet came in, and the chimney smoked so that they could not have a fire. She had lived there nearly a year, and the dust had never been removed, for the dustman seldom came down their "place," and she had to do what she could with the dust. A neighbour was then called, and she described the place in the same terms. She had lived in the "place" more than a year, and the dust had been only once removed. There was no dustbin, and there was no water to the closets. One reason for the dust not being taken away was that the dustmen would not take it unless they were paid, and they generally came at the end of the week when the people had no money. She added that in consequence of an inquest held there a short time since, and the exposure of the wretched state of the place, the parish had moved in the matter, and had summoned the owner of the "property" for his neglect. Mr. Newby was then called, and he said he had practised as a surgeon for thirty years, though he held no diploma whatever, and he maintained he had treated the child properly. The Coroner said Mr. Newby must be aware he was contravening the law, but that was a question for the Medical Profession; and as Mr. Newby was not legally qualified, he (the coroner) had instructed a gentleman to report upon the child and the place were it died. Dr. James Edmunds reported that he had made an examination of the place and the child's body. The attack of small-pox was a comparatively slight one, and was one not likely to have terminated fatally under ordinary circumstances, and the Medical treatment it received was such as would have been given it by Medical men. It was to be noticed that vaccination appeared to have been carried out very carelessly in this family, for of five children the vaccine matter had not properly taken in two. The result was remarkable,—the three properly vaccinated had escaped the disease though it had been in the family, and was in the neighbourhood; but the other two had taken it, and one was strongly marked while the other had died. With regard to the "house," it was a dilapidated tenement of two small rooms, with a small shed called a kitchen, behind. The rooms, if such they could be called, were connected by a rickety staircase, so cranky as to be quite unsafe. The roof let in the water, and the floor of the lower room, resting upon the earth, was a foot below the alley or court, and in many places the flooring was broken. The chimneys were so imperfectly constructed as to be likely to smoke, and they did smoke, so poisoning the lungs and preventing ventilation. There was a small yard of a few square feet, leading to a dilapidated privy, without water, with a large heap of stinking refuse surrounding it. There were no taps for water, but there were two orifices whence the water ran in once a day for twenty minutes, and it ran into a small rotten tub, without a cover. The whole yard was overflowed with water, for when the tub, the capacity of which was quite inadequate to the wants of a family, overflowed, there was no place for the water to run off, and the stink arising from the privy and the rotting refuse would be absorbed by the water in the tub, and which was thus rendered unwholesome, if not poisonous. He concluded by saying that these surroundings would account for the death of the child. The coroner and jury expressed their indignation that such tenements should be allowed to stand, and a verdict was returned "That death arose from natural causes, accelerated by the bad sanitary condition of the house in which the parents lived."

ON THE INFLUENCE OF SOCIAL POSITION ON LIFE.—It

is said proverbially that poverty favours longevity, because the poor are not subjected to the bad consequences of luxury and wealth. Dr. Majer shows the folly of the popular dictum. It has been proved by the researches of Benoiston, De Chateauneuf, De Villerme, Casper, and others, that the value of life is less among the impoverished than the rich. Thus, of an equal number of infants of the same age double the number will die of the poorer than of the wealthier class. Where there is the greatest misery, there is the greatest mortality. According to Casper, the mean duration of life among the better classes of Berlin is fifty years, but among the paupers thirty-two years only. The same writer compares the death-rate of the princely and noble houses, given in the 'Almanach de Gotha,' with the indigent of Berlin, and he shows that of 1,000 infants among the former, fifty-seven die in the first five years; but of the same number among the latter, 345. Whilst the half of the poor only have attained the thirty-second year of life, half of the noble have attained the fifty-second. During epidemics the poorer classes are in an especial manner decimated. That simple well-being prolongs life is demonstrated by the low rate or mortality among persons who "assure" their lives in the assurance offices. A fifth or sixth part o negro slaves die annually. But the mortality among th free negroes that serve in the English coloured regiments only 3 per cent., that of slaves being 17 per cent. The l rned professions, followed generally by persons of easy n ans, have an incontestable influence upon the duration of fe. Thus, the mean age of fifty-two French literary men was sixty-nine years. Physicians, according to Dr. Escherich, can not hope for a long life. At all periods of age they succumb in larger number than other professions. But the greatest mortality is during the early periods. Three-fourths die before fifty years of age, and ten-elevenths before sixty. Old men are rare among them. —'Annales d'Hiégiène Publique et de Médecine Legale.'—'Half-Yearly Abstract of the Medical Sciences,' &c.

RESEARCHES ON MARRIAGES OF CONSANGUINITY IN THE COMMUNE OF BATZ, NEAR CROISIE (LOIRE INFERIEURE).—Dr. Viennois spent a month in Batz, the residents of which have, for centuries, been in the habit of contracting marriages of consanguinity, and in living in nearly total isolation from the neighbouring districts. There were forty-six such marriages at the time, in the place. He inquired into the previous history of the husband and of the wife; he examined them and their children, with regard to their physical and intellectual development. He questioned the old members of the community also, and with these various materials he drew up tables which show that consanguinity has brought on no disease, no degeneration, no arrest of development, and that the stock has remained very handsome and very pure. —'Gaz. Hebd. de Med. et de Chir.'—'Half-Yearly Abstract of the Medical Sciences,' &c.

CHILDBED MORTALITY IN VIENNA.—At a late meeting of the Vienna Society of Physicians, Professor Späth stated, in a report of the Clinical Lying-in Hospital for 1864, that out of 8,761 deliveries there were eighty-six deaths.

DEATH OF DR. EASTON.—We are deeply concerned to notice the death of Dr. Easton, Professor of Materia Medica in Glasgow University. The doctor's health had not been for the last two years, so robust as formerly; but on the 11th inst. he attended to his professional duties as usual. The next morning, however, he was suddenly seized, and death ensued after about three hours' illness. Dr. Easton was extensively known and respected as an eminent practising physician, and an able and successful Medical teacher.—'Glasgow Herald.'

A LECTURE TO LUNATICS.—COLNEY HATCH.—MIDDLESEX COUNTY LUNATIC ASYLUM.—Dr. Sheppard, the medical superintendent of the male department, lately commenced his winter course of lectures to the patients. The subject was "Teetotalism," and he hoped they wouldn't look very serious if he began with a text:—"For how great is His goodness, and how great is His beauty. Corn shall make the young men cheerful, and new wine the maids." He said they would perceive at once from the quotation which way the wind blew. He was no advocate for teetotalism, and never had been. It was based upon wrong principles, and the substratum of all the arguments in favour of it was essentially unsound. The abuse of a thing constituted no valid reason for refusing to use it properly. The use of alcohol was an instinct, as much as was the use of tea or salt; and it was our duty to educate our instincts and not to suppress them. Tea was as susceptible of abuse as alcohol, though its effects were slower. The tea-and-buttered-toast section of society were martyrs to dispepsia, which would be remedied by the light wines of France now happily being introduced into this country through the wisdom of the legislature. These wines contained 9 or 10 per cent. of alcohol, instead of the 22 per cent. of bad port and sherry. The lecturer said he had never been drunk but twice in his life—the first time at the age of seventeen, when he was befoozled upon gin-punch by a wicked old Dorsetshire parson who ought to have known better; the second time, ten years ago, at Naples, when he took a strong cup of tea in the middle of the day upon an empty stomach. He took the latter at the wrong time and of the wrong strength, and his stomach and brain were as much on fire as if he had taken spirits. This is just the mistake made by the drinkers of fermented beverages in this country. They drink too much and they drink too strong, and at all times and seasons. The lecturer said he had lived for months together in towns in Germany, France, and Italy, and had never seen such a thing as a drunken man; and yet the ordinary beverage was moderately-fermented wine, both with breakfast, dinner, and supper, and the use of tea was almost unknown. Did those well-meaning total abstinence people reflect how the rigid carrying out of their principles would subvert the order of nature? It would involve discrowning the hills of their purple glories, and the valleys of their teeming produce. There were whole tracts of country—such as the sunny slopes of the Rhine and the Loire—as clearly marked out for the culture of the vine as were the sandy soils of Lancashire for the potatoe, or the barren rocks of Palestine for the olive. It was then shown that the persons most liable to acute disease and least able to bear up against depressing influence were drunkards and teetotalers, whilst the temporate men tided over the difficulties which beset the two extremes. In this high-pressure age the withdrawal of alcoholic stimulus from society would cause it to collapse in a fortnight. It would shrink up like a paper kite. The strong man would bow down in agony, and the fountain of life would be dried up for the unweaned child. After recommending a little beer for working men, with dinner and supper, condemning spirits as the real curse of this country, and showing how the upper classes had improved since the "old port" school had died out; after urging upon all of them temperance and moderation, the Doctor concluded as follows:—If we who bear rule and are called upon to treat disease in this place are not familiar with the evils of intemperance, I know not who can be. By it, how many good situations are lost, how many prospects ruined, how many characters undermined. By it, how many homes are broken, and how many hearts are broken down! Nor is this all. Do these miserable drunkards forget what they entail upon a future generation? How many of the sots of our day have received from others—if not the fatal heritage of disease, at least the proclivity to drink! How many of the idiots of this island are the brainless harvest of intemperate sowing! Excess of every kind, my friends, is bad. Too long a sermon is cruelty to a congregation. Too long a lecture is equally offensive, and will deprive me of what I am always desirous of securing—your approbation." The quiet demeanour of the patients at these gatherings is most remarkable, and the interest which they take in them is truly gratifying.—'Barnet Press.'

THE CATTLE PLAGUE.—A Committee of the Lords of the Privy Council assembled on the 13th instant to take into consideration questions relating to the cattle plague.

CHOLERA IN AN AMERICAN STEAMER.—The steamer 'Atalanta', arrived at New York, has been detained in quarantine. She had sixty cases of cholera on board, among which were fifteen deaths.

At the recent examination for Prizes in Materia Medica nd Pharmaceutical Chemistry, annually given by the ociety of Apothecaries, the successful candidates were— st. George Rolph Raine (Guy's Hospital), a Gold Medal; nd. William Barnett Burn (St. Bartholomew's Hospital), Silver Medal and a book.

At the Students' Medical Society at Edinburgh much discussion has occurred of the results of acupressure. It is tated that Professor Syme will try the method of temporary gature, described by Mr. Churchill in a recent number of his journal.

APPOINTMENTS FOR THE WEEK.

EDNESDAY, Nov. 22.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

HURSDAY, Nov. 23.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

RIDAY, Nov. 24.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, Nov. 25.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

ONDAY, Nov. 27.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metropolitan Free Hospital, 2 p.m.

UESDAY, Nov. 28.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

hotographs (coloured) of the Diseases of the Skin. By Alex. B. Squire, M.B. London: John Churchill and Sons.

ay on the Nature and Treatment of Cholera and Fever, with Medical Remarks on the Treatment of Cattle Plague; also n Appendix on Public Health. By James Tucker, M.D., L.R.C.S.E. Dublin: John Falconer; London: John Churhill and Sons.

the Means employed for Correcting the Inverted Image in he Retina of the Eye. By Joseph Swan. London: Bradbury, Evans, and Co.

andbook for Yellow Fever, and a Brief History of Pestilential holera and a Method of Cure. By Thomas Anderson, M.D. ondon: John Churchill and Sons.

heoretical Inquiry into the Physical Cause of Epidemic seases; accompanied with Tables. By A. H. Howe, M.D. ondon: John Churchill and Sons.

Address delivered at the London Hospital Medical College, d October, 1865. By W. Rivington, M.S. London: hn Churchill and Sons. Rivingtons.

's Diaries for 1866.

NOTICES TO CORRESPONDENTS.

requested that all communications intended for the Editor y be sent to the Office of the Journal, No. 20 King William eet, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause, and have made such arrangements as will prevent the possibility of a repetition of the same. Any gentleman not having received his copy as usual during the last three weeks, will be kind enough to intimate the same to the Publisher.*

A MEDICAL MAN.—The homœopathic system has been tried in the hospitals of Paris and Vienna, and has failed. We will endeavour to procure the exact dates at which the investigations were made.

INQUIRER.—The disease called *Elephantiasis græcorum* prevails very extensively in Norway and Sweden, and a monograph on the subject has been written and published by Drs. Boeck and Danielsen, of Christiania. Dr. Boeck is now in this country.

DR. T.—The newspaper has been received.

AMICUS.—We are not at all surprised that our remarks have not given satisfaction in the quarter alluded to.

MR. ALEXANDER FERGUSSON.—The letter of our esteemed correspondent appeared, together with some editorial remarks, in our number of October 25. We regret that the extra copies were not sent, but, as it will be perceived by a notice elsewhere, certain irregularities have occurred on the part of one of the persons engaged in our publishing office, and are now in course of further investigation. The copies will be immediately forwarded.

DR. J. M.—The case is published in our present number.

MR. R. T.—The persons in question swore that they were registered, and the magistrate had, or ought to have had, a copy of the register at hand to confirm or contradict the statement. The register is supplied by the Government to certain public offices and departments free of cost.

A HOMŒOPATHIC QUESTION.

To the Editor of the Medical Circular.

SIR,—Will you kindly inform me what is the answer to give to homœopaths when they argue thus:—Since infinitesimal doses of certain drugs—*e.g.*, the emanations of ipecacuanha—act on some persons with peculiar idiosyncrasies, why should they not act in disease?

I am, &c., STUDENS.

New Ormond street,
November 18.

[The answer is, that ipecacuanha acts only upon certain persons with peculiar idiosyncrasies, and this property is therefore an exceptional one. The emanation of flowers has been known to produce unpleasant effects, yet this is not a general property of flowers. But the homœopaths elevate their shadowy fancies to the rank of therapeutic *laws*.—ED. MED. CIRCULAR.]

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 78 FARRINGDON STREET, CITY.

and Navy Regulation Cases. Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera ce Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other t makers.——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second hand Surgical Instruments, ded for 6 stamps.

ESTABLISHED 1848.

Mr. J. Baxter Langley, M.R.C.S.

Eng. (late of King's College, London), PROFESSIONAL AGENCY, 50 Lincoln's-inn fields, W.C.

Country Practices.—Mr. Langley

begs to call the attention of young professional men seeking openings for practice to his Register, which, at present, contains a large number of very eligible openings, death vacancies, &c., in the country (with and without public appointments), requiring the investment of only a moderate amount of capital, yet offering a good prospect of fair and prompt returns. Applicants may rely that nothing will be recommended as an investment which Mr. Langley does not believe to be bonâ fide and suited to the circumstances of his clients.

Medical Investments.—Gentlemen

wishing to commence practice, and having capital at their disposal (from 100*l.* to 4,000*l.*), are informed that Mr. Langley has now upon his list upwards of 150 bonâ fide partnerships and practices for negotiations. Professional Agency. Office hours 11 till 4.

Liquor Folii Ricini, or Fluid Extract

of the Palma Christi Plant, for increasing the Secretion of Milk in Suckling Women.

Mr. GREENISH solicits the attention of the Profession to the above preparation, which is now in great demand.

Dose: One teaspoonful three times a day.

Prepared by THOMAS GREENISH, Chemist, 20 New st., Dorset sq.

Superphosphate of Iron and

SUPERPHOSPHATE of IRON and LIME.—Particulars of these new and valuable remedial agents will be forwarded on application, by Mr. Greenish, 20 New street, Dorset square.

Jozeau's Copahine Mege.—Copaiba

and Cubebs are doubtless the best remedies, but are of a repulsive taste and odour, and occasion colicky pains, nausea, and gastric disturbance. M. Jozeau has succeeded in rendering them perfectly innocuous by increasing all their curative properties. It has been adopted by the Paris Academy of Medicine after more than a thousand trials in Paris and the different London hospitals, viz., St. Thomas's, Guy's, and St. Bartholomew's, under the care of Messrs. Lloyd, Poland, and Legros Clark. —'Lancet, Nov. 6, 1857. The Copahine, which is in form of a pretty pink sugar plum, effects a cure in about six days. 100 Capsules, 4s. 6d.; post-free, 5s. 2d. — At G. JOZEAU'S, French Chemist, 49 Haymarket, London; 22 Rue St. Quentin Paris; and all Chemists.

Medical Fixture & Glass Warehouse.

—W. HAY and SONS, 24 and 25 Little Queen street, Lincoln's inn fields, beg to inform the Profession that they Fit-up every description of Medical Shops and Surgeries, and have in Stock a large assortment of New and Second-hand Drawers, Counters, Desks, Dispensing Screens, Bottles, Jars, and every requisite for the above.—A large Assortment of Medical Lamps.

James's Fever Powder, 4s. 6d. per

bottle; packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all wholesale Druggists.

Flour — (Essex) — Warranted free

from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs.) 9s. 8d. Households (recommended for bread-making), 9s. 0d.; Seconds, 8s. 4d.; Wheat Meal for brown bread, 8s. 4d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any railway station 200 miles. German yeast.

CHOCOLAT-MENIER.

The healthiest and most delicious Aliment for Breakfast known since 1825

ANNUAL CONSUMPTION EXCEEDS 4,000,000 lb.

Defies all honest competition.

Unadulterated, PURE, and highly nutritious.

Wholesale—23 Henrietta street, Covent-garden. Retail—BATTY & CO. 15 and 16 Finsbury pavement, E.C.; and all respectable houses.

TO THE MEDICAL PROFESSION.

Bragg's Charcoal Biscuits for

INDIGESTION, HEARTBURN, &c. &c., manufactured from the purest Vegetable Carbon. Sold only in tins, at 1s., 2s., 4s., and 8s. each, by J. L. BRAGG, Sole Manufacturer, 2 Wigmore street, Cavendish square, London. Also "IRON TONIC BISCUITS," in 2s., 4s., and 8s. Tins.

Chemists and others allowed a liberal discount.

Post-office Orders made payable at the Old Cavendish-street Branch.

Medical Transfer and Partnership.

30 BUCKLERSBURY, LONDON.

Mr. Orridge, Medical Transfer

Agent, Referee, and Valuer of Medical Property may be consulted, as usual, at the above address

Office Hours, 11 to 4.

Royal College of Physicians of LONDON.

FIRST PART of the PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination of Students who have completed their Second Winter Session of Study at a recognised Medical School will commence on Tuesday, December 5th.

SECOND PART of the PROFESSIONAL EXAMINATION.—An Examination of Gentlemen who are eligible for admission to the Second Examination for the Licence will commence on Tuesday, December 12th.

Registered Medical Practitioners, qualified before January, 1861, are admitted to Examination under Special Bye-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time.

Pall-Mall East, 1865. H. A. PITMAN, M.D., Registrar.

ARMY MEDICAL DEPARTMENT, Nov. 2, 1865.

A Competitive Examination of Can-

DIDATES for COMMISSIONS in the MEDICAL DEPARTMENT of her Majesty's Army will commence at Chelsea Hospital on MONDAY, March 19, 1866, at ten o'clock, a.m. There will probably be about thirty vacancies.

SUBJECTS OF EXAMINATION:

Obligatory.—Anatomy and Physiology. Surgery.—Medicine, including Therapeutics, the Diseases of Women and Children, Chemistry and Pharmacy, and a Practical Knowledge of Drugs.

Optional.—Comparative Anatomy, Zoology and Botany, with special reference to Materia Medica.

Candidates having the necessary qualifications to practise medicine and surgery under the Medical Act, and who are unmarried, and not under twenty-one nor above twenty-eight years of age, are eligible to attend.

Applications for the printed forms, which must be filled up by intending competitors before their names can be placed on the list of candidates, should be made (in writing) to the Director-General of the Army Medical Department, War-office, London.

J. B. GIBSON, Director-General.

S. V. R, 56° Over Proof.

First Quality, 20s. 6d. per Gallon.

This quotation admits of neither credit nor discount, and is for quantities of not less than two gallons.

HENRY BRETT & CO., DISTILLERS,
HOLBORN and REGENT STREET.

Hedges & Butler, Wine Merchants,

&c., recommend and GUARANTEE the following WINES:

SHERRY.

Good Dinner Wine, 24s., 30s. 36s. per dozen; fine pale golden and brown sherry 42s., 48s. 54s., 60s.; Amontillado, for invalids, 60s

CHAMPAGNE.

Sparkling, 36s., 42s.; splendid Epernay, 48s., 60s.; pale and brown Sillery 66s., 78s. Veuve Clicquot's, Perrier and Jouët's Moet and Chandon's, &c

PORT.

For ordinary use, 24s., 30s., 36s., 42s.; fine old "Beeswing," 48s., 60s. choice Port of the famed vintages, 1847, 1840, 1834, 1820, at 72s. to 120s.

CLARET.

Good Bordeaux, 18s., 20s.; St. Julien, 24s., 30s., 36s.; La Rose, 42s.; Leoville, 48s.; Latour, 54s.; Margaux, 60s., 72s.; Lafitte, 72s., 84s., 96s.

WHITE BORDEAUX.

Good Dinner Wine, 24s., 30s.; Barsac, 42s., 54s; Sauterne, 42s., 48s. 60s., 84s.

BURGUNDY.

Macon and Beaune, 30s., 36s., 42s.; St. George, 42s.; Chambertin, 60s., 72s.; Côte Rôtie, 60s., 72s., 84s.; Corton, Nuits, Romanée, Clos-de-Vougeôt, &c.; Chablis, 24s., 30s., 36s., 42s., 48s.; Montrachet and St Peray, sparkling Burgundy, &c.; Chablis, 24s. 30s., 36s., 42s.

HOCK.

Light Dinner Hock, 24s., 30s.; Nierstein, 36s., 42s.; Hochheimer, 48s., 60s. 72s.; Liebfraumilch, 60s., 72s.; Johannesberger and Steinberger, 72s., 84s., to 120s; Assmanshausen, a choice Red Hock, 48s., 60s.

MOSELLE.

Still Moselle, 24s., 30s.; Zeltinger, 36s., 42s.; Brauneberger, 48s., 60s. Muscatel, 60s., 72s.; Scharberg, 72s., 84s.; sparkling Moselle, 48s., 60s., 66s., 78s.

Foreign Liqueurs of every description. On receipt of a post-office order or reference, any quantity will be forwarded immediately by

HEDGES & BUTLER,
London: 155 Regent street, W.; and 30 King's road, Brighton.
ORIGINALLY ESTABLISHED 1667.

Kinahan's LL Whisky.

DUBLIN EXHIBITION, 1865.

This celebrated Old IRISH WHISKY gained the Dublin Prize Medal. It is pure, mild, mellow, delicious, and very wholesome. Sold in bottles, 3s. 8d. each, at the retail houses in London; by the Agents in the principal towns in England; or, Wholesale, at 8 Great Windmill street, London, W.—Observe the Red Seal, pink label, and cork branded "Kinahan's L L Whisky."

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON THE USE OF ICE IN HYSTERIA.

By HENRY SAMUEL PURDON, M.D., L.R.C.P. Edin.,

'hysician to the Belfast Dispensary for Diseases of the kin ; Assistant-Physician Belfast Charitable Infirmary, &c.

The advantages derived from the employment of ice in any nervous disorders cannot be overrated. We find it eful when applied to the spine, in tetanus, and lately re-mmended by Dr. Chapman in the treatment of cholera ; t as our inquiry lies with regard to its therapeutic value hysteria, I hope to be pardoned for passing over many seases in which it is used with advantage.

Hysteria, as is well known, most frequently occurs in males, and from its simulating nearly every form of dis-se, has well been called "a proteiform malady." In ne cases it appears to be hereditary.

The treatment of this affection has been, and still is, a puted point, some practitioners giving anti-spasmodics, ers volatile stimulants, warm purgatives, &c., but the edy which exerts a specific control over this disease is , and the late Sir Henry Marsh, of Dublin, used it suc-sfully in hysterical vomiting.

The physiological effects of ice, when the cold is not ense, are a diminution of vital activity, followed by re-ion, its direct or primary effect being the abstraction of oric, producing by this means a sedative action, and ening the sensation of pain.

ce, then, when applied topically, produces a sudden, in e cases gradual, impression on the nervous system, thing and allaying irritation, a result which is very de-able to be gained in the treatment of hysteria. In the lowing case ice was the principal agent used :—

Miss B., aged thirteen, of an irritable habit, often suffering n a slight indisposition of a neuralgic character, became subject of an aggravated form of hysteria, with pain and lerness on pressure over the spine ; bowels costive, e scanty, and appetite bad. Occasional delirium, fol-ed by deep sleep. Intolerance of light and sound were tant symptoms. One curious symptom present in this was headache, which subsided daily at a certain hour. paroxysms commenced in the lumbar region, lasting considerable violence for about one hour.

cure was obtained by means of ice, the spine being sponged with iced water, and the cold kept up with ded ice for about two hours daily. After the lapse of night, the paroxysms became of shorter duration and frequent, a cure eventually taking place.

the action of the ice be too energetic, warm drinks be administered, such as coffee, or even weak tea, act slightly as stimulants and occasion no evil s.

SCIENTIFIC ARTICLES.

SONING BY NITROBENZOLE AND ANILINE.

('Chemical News') have already given an account of of the cases of poisoning by nitrobenzole which have ed—and they have been very few—so that it will be essary here to do more than refer to some of the chief arities of the action of this poison. For a long time it became an article of commerce, nitrobenzole was own to be poisonous. Some of it was exhibited as a roduct in the Perfumery Department of the Exhibi-1851, and the Jury of that section, reporting thereon, at it was "probably capable of application in confec-tionery and cookery, as its flavour resembles that of bitter almonds, without containing any prussic acid." It was first shown to be a poison in 1856, but before that time the stupefying effects of its fumes had been noticed by workmen employed in its manufacture.

The first case of poisoning in the human subject occurred in 1860, and was investigated by the author of the paper we notice. A workman spilt some of the liquid upon the front of his clothes, and thus went about breathing an atmosphere charged with the vapour. In the course of four or five hours the man began to feel ill, and in nine hours he died. In all the other cases recorded (only five) some of the liquid has been swallowed, but in none, probably, more than a few drops. All the cases, with one exception, have proved fatal.

With regard to the symptoms, we need only say that they are those of a powerful narcotic poison. The patient, in general, at first becomes drowsy, some convulsions afterwards occur, profound coma gradually comes on, and the sufferer dies.

An investigation of the effects of the poison on animals led to some interesting observations. The most curious and, indeed, startling of these is the circumstance that when but a small dose of the poison is administered, the effects are not developed until the lapse of a considerable time,—in some cases three or four days. Some discomfort which the animal seems to feel at first passes off, and it remains to all appearance perfectly well until seized with a kind of epileptic attack. Paralysis of the hinder extremities succeeds, which is followed by severer symptoms, and the animal dies, it may be as long as nine days after having swallowed the poison.

When death is rapid, the smell of nitrobenzole is perceptible in every tissue of the animal's body ; but in lingering cases no vestige of the smell remains. It has been found, in fact, that the nitrobenzole becomes changed into aniline in the living body—a most important fact, as Dr. Letheby remarks, to the toxicologist, the chemist, and the physiologist.

The effects of aniline are closely analogous to those of nitrobenzole ; but the symptoms do not seem to be delayed, as in the case of the latter poison. On this point, however, we cannot speak with certainty, for Dr. Letheby appears to have administered aniline in rather large doses.

It is a remarkable and, so far as our memory serves us, an unique circumstance, that while analine itself is an energetic poison, its salts are quite innoxious. The sulphate has been administered in large doses—in one case at the London Hospital nearly an ounce was given to a patient in the course of a few days—and the only effect observed was a colouration of the skin, gums, and nails, which all became more or less purple.

We have seen before that nitrobenzole is converted in the body into aniline, and the effects of aniline just described appear to show that aniline is also converted into some of its coloured derivatives.

"The chemist perceives that the nitrobenzole has been changed, by a process of reduction, into aniline, that it has lost it four proportions of oxygen, and has gained two of hydrogen, passing from $C_{12}H_5NO_4$ to $C_{12}H_7N$, and he also perceives in the leaden hue of the face and the *mauve* tint of the lips and nails that subsequent oxidation of the aniline has been effected. The physiologist recognises the fact that these changes have occurred in different parts of the body, that the process of reduction has taken place in the interior of the system, and that the subsequent oxidation has been merely a surface effect." However this may be, these curious facts seem to throw some light on the processes going on in our bodies, and suggests investigations from which further information may be obtained. The mauve colouration speedily disappears from the surface of the body : in what form is the aniline compound eliminated ?

We have already given Dr. Letheby's process for the detection of aniline and nitrobenzole in organic matters, and need now describe it very briefly.

The matters to be examined are bruised in a mortar with a little water, slightly acidulated with sulphuric acid, and

then submitted to distillation. Unchanged nitrobenzole passes over, and may be recognised by its smell. The residue in the retort is treated with strong alcohol to extract sulphate of aniline. The alcoholic solution is treated with slight excess of subacetate of lead to remove organic matters, and excess of lead is got rid of by treating the filtered solution with sulphate of soda. The filtered solution from sulphate of lead is now made alkaline with caustic potash, and distilled to dryness in an oil bath. Aniline is found in the distillate, and may be recognised by the nascent oxygen taste.—'Chemical News.'

CYCLOPS' TWENTY-NINTH LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—Have physiologists thoroughly understood the value and uses of adeps, or fat, or sufficiently explained why it is found at various parts of the body and not at others? It has been asserted, and believed as truth, that it is a secretion from the blood, as every other substance and fluid has been. Notwithstanding the minuteness of the blood-vessels spoken of, through which this deposit is to be furnished, they say that the adeps, or fat, is conveyed to the "circumference of the column of blood in these vessels, and transudes through their pores." Now, I do not believe anything of the kind; nor, for one moment, think that this peculiar and useful structure can either be a product of the blood or is capable of supplying it with any of its *bona-fide* properties. It is found everywhere where it is required, and "varies in quantity and consistence in different parts of the body and in different persons." "It is found in considerable quantity between the interstices of the muscles, along the blood-vessels, near the articulations, and in the vicinity of certain organs, as the eyes, the kidneys, and the breasts." "In the eyes it is soft and fluid, and about the kidneys of the consistence of suet." "Between these two extremes there are many gradations, and not exactly the same in any two different parts of the body, the high temperature of which maintains it in a semi-fluid state." "Where it is absolutely fluid it contains no oily substance." "In these cases cellular tissue yields more readily to extension, and membranes are more capable of expansion." "No real adeps is ever found in the skull." "Its quantity is about one-twentieth of the weight of the whole body, varying, of course, in age and sex." "When digestion and absorption are performed with great activity, fat accumulates in proportion." "It is imperfectly animalised; is analogous to the oils extracted from plants; contains very little azote, and much hydrogen and carbon, yielding on distillation water and carbonic acid; varying in its proportions without impairing the order of the functions; it repairs waste, as is seen in hybernating animals, and is greater in the graminivora than the carnivora; the fat of the former being consistent and firm, and that of the latter completely fluid." "A corpulent man on having his diet reduced; the bulk and weight of his body diminishes from the absorption of fat, *which supplies the deficient quantity of blood*." "Adeps may therefore be considered as a substance in reserve by means of which, notwithstanding the small quantity of food, and its want of nutritious qualities, Nature finds wherewith to repair the daily waste." Such, then, is what physiologists say of the fat, always premising that it is a product of the blood, and so deposed from it that it is as it were a capital to be used again. It is a very pretty theory if it was true, and for want of a better it serves all the purposes of the present day with its limited amount of knowledge; but it will not, I think, stand the test of a future.

Physiologists further say that "sebaceous acid is obtained from it by distillation, formed by the combination of *the oxygen of the atmosphere with the hydrogen*, the carbon and the small quantity of azote which it contains, which nearly constitutes it a vegetable acid." "Fat has a great affinity for oxygen; it deprives metallic oxides of a part of their oxygen; in proportion as it absorbs oxygen its density increases." "The cellular system may be looked upon as a vast reservoir; the fat preserves the body in its natural temperature, being a bad conductor of heat, fat persons scarcely feeling the most severe cold; Arctic animals, besides being clothed in a thick fur, are provided with a considerable quantity of fat; so are the fish in frozen seas, and all kinds of whales." "By its unctuous qualities, fat promotes muscular contraction, the motion of different organs, and the free movement, on each side, of different surfaces; it stretches and supports the skin, fills vaculties, and gives to our limbs rounded outlines, &c." "It envelopes and covers over the extremities of nerves, so that if they are too much denuded of adipose and cellular tissue are exposed to external actions as injurious as the rays of the sun to a plant torn up from its native soil." "Both excess and deficiency of fat are more or less injurious to the system." "*According to modern chemists, the use of the fat is to take from the system a part of its hydrogen.*" "Whatever moderates the activity of the circulating system, tends to bring on adipose plethora, such as indolence, hæmorrhages, &c., while great energy of the body causes emaciations." "The medullary juice is a very liquid fat, yet the marrow in bones has different density." "*The secretion of marrow is like that of fat, a mere arterial transudation; it is performed by the medullary membrane* lining the inside of the central cavity of the long bones; which in health gives no mark of sensibility; in diseases of bones after venereal or mercurial actions, the membrane becoming highly vascular, exquisite sensibility then arises."

It will be seen from these extracts that it is the undoubted opinion of physiologists that fat is a secretion from the blood most ingeniously set forth by the gratuitous theory, that the column of blood in the minute vessels, throw all sebaceous matter to their surfaces on purpose to aid the exudation in all parts where this element is required, and transuding it from the few and minute arteries in the medullary membrane, to make marrow. But it does not show why blood in other vessels, endowed with the self-same fatty properties, fails to deposit these where they are not wanted, or why this is not done. Now, all these doctrines put the student of ancient dogmas very much in mind of what anatomists and physiologists once said of the uses of the blood, or as much as was known of it after several centuries of patient research, before the time of Harvey. But when he stepped in and completed the circle or the last and ultimate step, then it was found that they were only pretty theories, if not mere nonsense. Nevertheless, this violence done to received opinions could not be borne easily; it so shocked the general community, that no anathemas or abuse were gross enough to be dealt out against the bold innovator. Now, it is just the same with the fat and its uses. If we can only arrive at some ultimate step far more consistent with truth, we should let in a great flood of light on many subjects which now form stumbling-blocks at every step we take, both in physiology and the practice of medicine. The subject merits serious consideration, and as I have extracted the pith of what is said, and really believed in, I do not see how I can treat of the glands without first disposing of this subject. Can it then be possible for the blood to secrete such an immense quantity of fat shown to exist in body, and if it did, how could the minute arterial vessels support it, considering they never permeate the fat at all? Now, fat could not co-exist without a covering membrane; this membrane is very different to fat, it is highly organised, and what is called animalized, while the fat is an unorganised non-animalized mass. Take the fascia, then, which invests it, and compare it with what it invests; there is no analogy between them; a proof, I think, of what I have already advanced, that the arterial blood can only supply structural powers. Fascia, or skin, is a structure; but fat is only an inspissated liquid. Fat being found where it is, shows that it must be formed in a far different way, because it is, and so readily everywhere, and in the living body is always in a certain state of fluidity, implying that the fluid or rather aqueous portion is always being used up in some way and must be renewed as constantly. The quantity taken for the mere lubrication of the muscles, like grease to machinery or axles of wheels, must be enormous; yet, where most fat it is said to contain no oily substance. What then does it contain? No doubt as pure and aqueous matter as it is possible to conceive, with the smallest admixture of some

matter, such, for instance, as the tears, mere brackish water. The pain of a tooth-ache will sometimes produce a natural insalivation, and water as pure as tears will stream from the mouth. The cellular tissue is ever ready by any bodily exertion to pour this aqueous matter through the skin in the shape of perspiration. But let us reflect on what state of perspiration some persons are subjected to; the greatest, perhaps, are the coal-whippers, who work only in their trowsers, but their labour is so immense that I have seen them in puddles of their own sweat, and while the dust of the coals continually powdered their bodies. the streams of perspiration ran down them striping them like zebras. Can physiologists for one moment say with any justification that this immense sweating is a robbery of the blood and that it is made from the minute arterial vessels they speak of. Why the very largest vessels in the body could not make the continued quantity thus exuded, and if they did, in what condition would these coal-whippers be at the end of the day? On the whole their muscular power is more developed than lessened. There is no ingenuity in the world that can justify the present belief. Fat forms about the "twentieth of the weight of the body, and contains much hydrogen and carbon;" this is all true, but then physioligsts say, "it repairs waste as is seen in hybernating animals." Now this cannot be, for during the winter months these animals waste in every way, both in muscle and fat. The great mistake made in all this seems to me to be the wrong estimate taken of the uses of the fat. Granted that it is wanted for combustion; yet this simply means an internal stove everywhere for the due formation of sufficient caloric for the uses of the body in its living state. The next is the prime use made of the fluids, for it is impossible for animal life to exist without them; so that a long hybernation is merely that time which an animal can live by its own caloric and moisture in a perfectly quiescent state. When it ceases to do the former, or has not enough moisture within itself, the natural conditions would be fever and death. Now why does not the blood continue to make fat during hybernation? Simply because it is too plain that it cannot do so. Some will say it is because the animal is not consuming any food, and therefore no new elements of fat are taken into the system. This is poor logic, for on the other hand the animal has no stools, and it would be as natural to say how can it exist without any actions on its bowels. Physiologists somehow approach the truth even if they do not quite hold of it, for they say that fatty acids are a combination of *the oxygen of the atmosphere with the hydrogen*. Now we know where the one is obtained, but where does it get the other except from the body itself. This I have shown to be the prime use of the fæces to furnish, and that it is the combination of the hydrogens made by the body, meeting oxygen everywhere except in the colon itself, that an immense amount of aqueous fluid is formed in the body in every twenty-four hours, which is as clear as noon-day, never was eliminated from the blood. Now let us go one step further. Fluids in the body have a great tendency by natural law to condensation, and nothing can be more easy of solution than those which are formed by the union of the oxygen of the atmosphere and the hydrogens of the fæces, mixed as they are with carbon and other animal matters to do this and form adeps or fat as an inorganic mass, entirely independent of the blood. Thus nature having made this store, so condenses it on those parts only where it is required and where it is not, she prevents its deposition. She therefore excludes it from the lungs, the liver, the spleen and the brain, and probably other parts, but these principally. If, however, physiologists will still teach the doctrine of its being a formation from the blood, why does not the blood, going to these parts which are known to be excluded from fat, deposit fat there as well as at other places? They say also that it supplies waste, when in truth it also prevents waste. This is why fevers have never been properly understood. Directly a fever sets in, that moment there becomes an absorption of fat with a consequent loss of the aqueous supply to the body. Nature, therefore, endeavours by conserving the fæces to get all the hydrogen she can; but oxygen being in excess together with carbon, little or no moisture is made, while fatty depositions cease all at once, notwithstanding that the blood remains exactly what it was in every respect. Now, as soon as hydrogen can be formed in sufficient quantity for the oxygen taken into the body in every way, then gases meeting in due proportions, aqueous fluids are again formed and fatty condensations take place, and then the fever subsides as a natural sequitur. I ask those who have watched fevers with observing and scrutinizing eyes, and witnessed the shrunken aspect of the patient just at that time when the fever has somewhat abated in its character; how sudden an alteration has taken place, so that they have almost involuntarily explained, "the patient looks better, he will do now." Are these changes then due to the blood or to the gases? I maintain the latter, for it is to them and their equilibrium of action and union in the system that the drawn sunken countenance becomes fuller, and that they again form those fluids which are, and always must be made by them, independently of the blood. As the patient gradually recovers and puts on a plumper appearance and aspect, it is due to the inspissation of these fluids forming fat in cellular tissue, and round about the glands; but which nevertheless in itself is always changing in character. It is in fact the matrix for the diluents which nature is always making and always requiring, and which holds them, retains them, and only parts with them to suit her own purposes by her own wise laws.

I will further illustrate these facts in my next.

I am, &c.,

CYCLOPS.

LEGAL INTELLIGENCE.

TRIAL OF ROBERT HUNTER.

(*Before Mr. Justice* BYLES.)

On Friday morning Robert Hunter, commonly called Dr. Hunter, surrendered to his recognizances at the Central Criminal Court to answer an indictment charging him with rape.

The first witness called was the prosecutrix, Annie Merrick. With the permission of the Judge she was allowed to sit while giving her evidence. She said, in reply to her counsel, Mr. Butler Rigby,—I am the wife of Mr. Samuel Merrick, of 52 Upper Baker street. He is a tobacconist there. Previously to September last I had been suffering from consumption. In that month I consulted the prisoner, and saw him at his house from time to time up to the fourteenth of October. When I first saw him he examined me, and I asked him if he thought he could cure me. He said he could, and that in about two months he would make me as well as ever I was in my life. I gave him a guinea on that occasion, and he told me his terms would be 5*l.* 5s. a month. I said I would see whether I could afford them. On the following day my husband called and paid him 5*l.* 5s. I always went to Hunter according to the arrangement I had made. He did not come to me. On the fourteenth of October I went to him about eleven o'clock. I am sure it was on the fourteenth. I rang at the door or knocked, and I was shown into the waiting-room. A great many patients were there, and I waited more than two hours. I then saw the prisoner in his room on the first floor. He was quite alone. He asked me how I was. I said I felt the pain in my side much worse. He told me to sit down and, he then asked me to inhale something with an instrument which was on the table. There was a vapour coming from the instrument. I inhaled it for about five minutes, and he then took a small bottle from the table and poured some of the contents of it into the instrument which was on the table. I was inhaling the vapour from one end at the time he did so. A few minutes after he had used this bottle a very strange feeling came over me. He had poured the contents into the back part of the instrument, and while the vapour was still coming

out at the other end. It was a stupifying feeling, but I did not feel it so much then as afterwards. It increased. It was a powerless feeling. I retained my consciousness. He then said he would examine the pain in my side, and, it being low, he put his right hand up my clothes to do so. He remarked how much better my lung was, and that he hoped soon to get me about. All at once, while I was sitting on the edge of the chair, he threw me on the back of the chair. It was a kind of position that left me perfectly helpless. I could not move. He then committed the offence with which he is charged. For a second or two I was perfectly powerless. I struggled as much as I could to get away from him. He put his head and mouth over my face, and began kissing me in the most passionate manner, so that I could not scream. I got from him at last, and the chair being on wheels it flew back against a sofa. I took up my gloves and ran towards the door; but it was fastened by a bolt. I turned round and he was coming towards me. He said he hoped I would not think anything of what he had done; but I demanded that the door should be opened. He himself, then unfastened the door, and I went direct out of the house. On leaving the house I stood for a moment to see if I could get a cab, as I was quite unable to walk. I could not see one, and I went to the house of a friend of mine, Mrs. Sharland, about a minute and a half's walk from where I was. I remained there about ten minutes, or scarcely that. I came out and walked partly home along Quebec street. I saw a cab in the distance, and hailed it. On the way I called at Hunter's for an embrocation which he had prescribed for me. The servant gave it to me, and I got into the cab and went straight home. I saw my mother when I got home, and I made a complaint to her. It was then about two o'clock, or a little past. I remained at home after that. I took to my bed, which I kept for a fortnight.

Mr. Rigby.—Did you make any complaint to your husband?

Witness,—I was unable to do so. She continued,—During the time I was in bed my mother and a nurse attended me, my mother sleeping with me at nights. I had not the slightest communication with the prisoner after that. My mother went to him to ask that a doctor might be sent, and Dr. Willes was sent. I had not seen Dr. Willes before. He came to see me on the following Monday morning, the assault having been committed on the Saturday. He attended me three times, Dr. Melville came afterwards. He was one of the visiting doctors from Hunter's.

Mr. Rigby.—When was it you made the complaint to your husband?

Witness.—I first told him of it on the Monday fortnight after it happened.

Did you make a full complaint of what had taken place?

Witness.—No; I did not tell him all.

Mr. Rigby.—Did you at any time make a full disclosure to him?

Witness.—Yes; about two o'clock on the morning of Thursday, the 2nd of November.

Cross-examined by Mr. Serjeant Ballantine.—I had inhaled on several former occasions at Hunter's. I also inhaled at home, and I received an instrument from him for that purpose, but quite a different one from that I saw on his table, and I was also supplied with medicines by him. The terms were six guineas for the first month, and five guineas a month afterwards. I paid six guineas, including the guinea on the first day. The room in which I was with Hunter was a front drawing-room in Upper Seymour street, with houses right opposite, and I believe folding doors separated the room from another room. The patients always sit below. The chair was a low one with a high back, on wheels, and with no arms. The process was to sit on the chair and inhale from an apparatus below and supplied from behind. He pushed the chair back to examine my side. He was on his knees on the ground in front of the chair. I could not at first see what he was doing for my dress. I did not know what was about to happen until he began the assault. He was talking to me up to the very moment of it.

Sejeant Ballantine.—Do you mean to represent that the matter was completed?—No, it was not.

Did you struggle at all?—Yes, I did; and that was the cause of the chair going back.

Was there anything to prevent your screaming?—His face being upon mine did; but not after the chair went back. I was unable to scream. I was quite powerless, and my only object was to get out of that house.

Were you unable to scream?—I did not think of it.

Then it was not that you were physically incapable of screaming?—I did not try. I was too stupified to think of anything but to get out of that house.

Where was the house at which you called?—At the corner of Quebec street; you can see it from the prisoner's house.

I see in your deposition before the magistrate you said you did not scream because you did not like to make a "scene" in the house, you having been violated in this manner?—I really was so surprised and so weak that my only object was to get home to my husband, I never said I ran out of the house, but that I got out of the house as quickly as possible. Witness continued.—The house to which I went at the corner of Quebec street is a public-house, kept by Mrs. Sharland. She did not come down stairs until I had been there a few minutes. I first saw her barmaid. Mrs. Sharland is not here. When I was first examined before the magistrate I declined to give her name, because I did not think it necessary to tell her about such a disgraceful affair, I did not wish to bring in her name. Hunter had prescribed for me before the assault. When I went to him on the 14th of October he asked me how my side was. I said "Much worse," upon which he said he would give me an embrocation to make a blister, and he wrote a prescription and gave it to a man-servant. He said, "Before you go I will just examine your side." That was the first time a blister had been ordered me. It was for the embrocation I called. I have not had any communication with Hunter since the assault.

Serjeant Ballantine.—Neither written nor verbal?—I don't think I have.

Will you swear you have not?—Not to my recollection. I think if I recollect right the blister was not strong enough, and I think I wrote to tell him, and to ask him to take the embrocation a little stronger. I wrote to him on the afternoon of the same day.

Was that after you had told your mother he had committed a rape upon you?—Yes.

Is that your letter?—Yes.

The letter was read by the Deputy-Clerk of Arraigns as follows:—

"Dr. Hunter.

"Dr. Sir,—I think there must have been some mistake in my medicines, as I understood from you that you had prescribed something to make the blister. I only received a bottle labelled 'embrocation,' which I have put on my side without the least effect. I have sent the remainder of the bottle, and should feel obliged by your sending me word if it is what you intended for the blister. I am in such dreadful pain, or would not trouble you so much.

"I beg to remain yours obed'ly,

"52 Upper Baker street." "ANNIE MERRICK.

By the Judge.—That was sent on the same day on which the assault was committed, and about an hour after I had told my mother.

Cross-examination resumed.—I had the embrocation put on as soon as I got home; it had not the least effect. I tried it for an hour, and then gave it up. I wrote the note when I was in bed, and at my brother's suggestion. I had told my mother about the assault, and she begged me not to say anything about it in the letter, as I should have to tell my husband, and Hunter might give me something to injure me. Besides, I wanted still to have the benefit of the month's advice, for which I had paid. I was not aware until now that I had addressed him "Dear Sir." When I made this charge I know there was a charge against my husband and brother for an assault on Hunter. My husband keeps a cigar shop in Upper Baker street. He has done so for about six months. He had previously been for

about three years a traveller for a Mr. Parry. He (my husband) was bankrupt about twelve months ago. After that we lived in apartments at Brompton, and afterwards in Portland street. I don't know a person named Goddard. I have relations in Gloucester of that name. My brother's name is Frederick Goddard Jones. I have never heard of his calling himself Dr. Goddard. I came from Tewkesbury. My brother was once a policeman for about nine months at Cheltenham.

By Mr. Serjeant Robinson.—I was twenty-six years of age on my last birthday. At one time I kept a boarding-house in Conduit street, paying 190*l.* a year rent. I was there three years, and it was only on account of my husband's bankruptcy that we left. Many persons of rank and title lodged with us there. When the letter was written to Hunter I had not made any communication about the assault to my mother. I had mentioned the matter to my mother, and to her alone. I could not scream when the prisoner was committing the assault. What I had inhaled I believe prevent me. I could not scream because I was utterly powerless, and stupified too, and I believe that was from what I had inhaled. On no other occasion had he put anything into the instrument while I was inhaling the vapour.

The chair was produced in court, and identified by the witness, as was also the inhaling apparatus.

Elizabeth Jones, examined by Mr. Serjeant Robinson.—I am the mother of the prosecutrix, and keep a boarding-house in New Bond street. I recollect her coming home from Hunter's on the 14th of October. She reached home after two o'clock. She was crying, and made a complaint to me of some violence that had been done to her. She appeared to be very excited. She called me upstairs and made a communication to me. In about an hour afterwards she took to her bed. On Sunday, she being very much worse, I went to Hunter's and saw a servant maid. It being after four o'clock I found no Medical men there. I went on the Monday, and after waiting an hour and a half, I saw Hunter, though I did not wish to see him. I asked for a visiting doctor to come to my daughter as she was dangerously ill. He directed Dr. Willes to go. Dr. Willes came shortly afterwards and saw her two or three times. She became very much worse. I was nine nights attending her without having my clothes off. There were times when she was unconscious. The Sacrament was administered to her, and I was present. That was about a week after this affair. She was ill for a fortnight after that, and then she improved.

Mr. Serjeant Ballantine.—This is the first time I have been examined in this matter. I was not examined before the grand jury. On the Saturday I assisted in putting my daughter to bed. About an hour she fancied the embrocation was not operating, and I recommended her to write to the doctor. She had before that told me Hunter had grossly insulted her, and after that she told me all about it. She had been an hour in bed before the letter was written. I thought Hunter had made a mistake as to what he had said to her. She wanted to tell her husband about the matter, but I would not let her tell him. When I went to Hunter on the Monday I did not complain, because I was afraid he might give her something to injure her, if he knew I had told what happened. I knew the matter would have to a trial. I did not tell my husband or my son, as for several days we thought she was dying. The first night I saw my daughter she told her husband. She had often threatened to do so before. Her husband when he knew it threatened to shoot Hunter.

Re-examined.—When the embrocation was put on she was suffering great pain. Her screams were frightful.

Emma Wood, examined by Mr. Rigby.—I am in the service of Mrs. Sharland, who keeps the City of Quebec tavern in Quebec street. I remember Mrs. Merrick coming there on the 14th of October, between one and two in the day. She seemed very much excited. I saw her in the bar-parlour. Mrs. Sharland, who was upstairs dressing, was not present at first. Mrs. Merrick was not with me more than five minutes.

Mr. Serjeant Ballantine.—The landlord is dead. Mrs. Sharland went out of town yesterday morning. I don't know where she has gone to. I only know Mrs. Merrick by her coming there occasionally. She did not see Mrs. Sharland more than three minutes. I have not seen Mrs. Merrick since. A Mr. Butler came and gave me a subpœna on Sunday evening last. Mrs. Sharland was then out. I told her I had been subpœnaed when she returned. I did not know Mrs. Sharland was going out of town until yesterday morning, when she had a letter.

Re-examined.—Mrs. Sharland has kept the Quebec Tavern many years.

Frederic Goddard Jones said he was the brother of Mrs. Merrick. He was at the house on the 14th of October, and recollected his sister coming home. She was crying, and she lay down on the sofa at the back of the shop. She asked her mother to take her upstairs. No communication was then made to witness by her as to what Hunter had done. He did not know what had happened until the morning he went to whip Hunter.

By Serjeant Ballantine.—Witness had been a policeman at Cheltenham for about eighteen months. He resigned his situation. He had previously been an apprentice to a carpenter, and had been with a confectioner. He was not twenty when he entered the police. As a boy he was nicknamed "Dr. Goddard," but he had never assumed that name. His brother, with whom he lived near Tewkesbury, had charge of a lunatic patient. Witness had not.

By the Judge.—I went to Hunter's on the 2nd of November, and Mr. Merrick followed immediately afterwards.

Samuel Merrick, the husband, was called by the counsel for the prosecution, but not examined by them.

In reply to Mr. Serjeant Ballantine, he said,—On October the 30th I went to Hunter's and saw him. He then said he could not allow further attendance unless the fees were paid. My mother-in-law did not know I had been to Hunter. I went to him in consequence of Dr. Willes saying he wanted to see me. I had previously paid Hunter six guineas. He said he should require the money down before he further attended my wife, and I arranged it should be paid. I did not pay it because my wife would not have his attendance. I had been bankrupt shortly before. I paid nothing, because they seized my furniture. I owed my last doctor something—probably 18*l.*, and I left Conduit street and Brompton owing a good deal of money, none of which I have paid. I then took a cigar shop, and my wife served in it.

By Serjeant Robinson.—When Hunter asked for money for further attendances I had not heard of what he had done to my wife. On Monday, the 30th of October, when I saw Hunter I had made up my mind to pay 5*l.* 5*s.* more, but my wife said she would not have anything more to do with him, as she had been grossly insulted by him. She did not make a full disclosure to me until very early in the morning of the 2nd of November. After I had heard that, and on the morning of the same day, I went with my brother to Hunter's with a horsewhip.

The prosecutrix was called at the request of the judge, and in reply to questions by him said, that when she went to the door to get out she found it fastened with a bolt. She saw Hunter unfasten it. When he gave the prescription to the servant for the blister he shut the door and bolted it. That was about five minutes before the assault, and witness was inhaling at the time.

Mr. Serjeant Ballantine addressed the jury for the defence, after which Mr. Justice Byles, in summing up the case to the jury, said the indictment charged the prisoner with having feloniously assaulted Annie Merrick, and against her will violently ravished and carnally known her. The case was a peculiar one, and was wanting in some of the circumstances and elements which usually accompanied most cases of this nature. Ordinarily in such cases the question was whether the women consented. No such issue was raised here. The defendant alleged that the assault never took place, and that the story of the prosecutrix was a wicked invention from first to last. And certainly he never remembered a case in which more fearful wickedness was imputed by each party to the other. On the one side it was said that not only had the defendant committed a rape, but a rape

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause, and have made such arrangements as will prevent the possibility of a repetition of the same omission. THE MEDICAL CIRCULAR.

ICE-BAGS IN CHOLERA.

It is really too bad to find all our hopes disappointed, just when we imagined that they were about to be realized. We were told in the most positive manner a week or two since, in the columns of the 'Times,' that the homœopathists had found out the cure for the Rinderpest, and that it was only the obstinacy and blindness of the so-called "allopathic" practitioners that prevented the European public from deriving the benefit of this great "discovery" in the liberation of their flocks and herds from a scourge which is but too tangibly affecting the welfare of the public. But we are now told by the 'Lancet,' "on authority," notwithstanding the assurances given by its friend and patron of the daily press, that the so-called homœopathic treatment of the cattle-plague is a mere humbug, that it has no power whatever over the disease, and, even in the cases selected by the infinitesimal gentry, that it has failed altogether. The unfortunate disciples of Hahnemann are even deprived of the poor consolation of having a grievance, for it turns out that their assertions as to the obstacles thrown in their way by the "allopathists" are quite destitute of foundation, and that every opportunity has been afforded to them to test the merits of their treatment.

But a still more severe disappointment meets us in the collapse of the ice-bags, which have been proclaimed in the leading daily journal as "a discovery" for the cure of cholera, and the merits of which have been exhibited in the largest type, and at the very time when the greatest alarm existed in the public mind as to the approach of the dreaded visitor. It is, of course, quite useless to expect anything like science, far less Medical science, to have any voice in the editorial management of the 'Times,' which, as far as sound or solid information is concerned, is a mere *ignis fatuus*, which "leads to bewilder, and dazzles to blind," and so long as its columns can attract a transient notoriety by the proclamations of some infallible cure for consumption, or small-pox, or cancer, or cholera, or some other formidable malady, so long are its conductors perfectly satisfied that they have performed their duty to society and to mankind. It is of no importance to them whether, by such means, the minds of the weak and the credulous are deluded and their pockets evacuated, or whether pretenders and shallow reasoners in and out of the Profession are raised into unmerited notoriety and fame, while cautious and learned physicians are insulted, abused, or neglected: no, the article serves its temporary purpose, and some new forms of empiricism start up, like the heads of the fabled hydra, to replace their predecessor.

But this week we have something to say of one of our own contemporaries, whom we are at a loss to know how to treat, whether to blame him for his former credulity, or to praise him for his present candour. The theory and practice of the ice-bags, as is well known, were originally promulgated in the columns of the 'Medical Times and Gazette,' not, indeed, in the form of editorial articles, but in such a prominent position in the Journal, as to imply a belief, on the part of the conductors, in the value of the invention, and the application of the agent. The theory, indeed, was so ingenious, if not plausible, and the results were said to be so successful, that even the 'Lancet' actually seemed to vie with its contemporary in giving the widest publicity to the new therapeutical appliance, and Dr. Chapman was in the position of Captain Macheath between Polly Peachum and Lucy Lockit, where he sings: "How happy could I be with either, were t'other dear charmer away;" the ice-bags were patented, and were proclaimed, we verily believe, in many quarters, as an infallible remedy for almost every disease under the sun. Epilepsy, and the whole train of nervous diseases, were at first the only complaints supposed to be amenable to this peculiar treatment, but it was very soon found that such a domain was far too narrow for the jurisdiction of the ice-monarch, and presently all the host of female complaints and irregularities were found to yield, in a magical way, to the same influence; and then there was an easy transition to sea-sickness, and finally to cholera, and all the train of abdominal diseases. We must say, in justice to the 'Times,' that although the "discovery" of the ice treatment of cholera was first made known in its columns, the trumpet of the ice-bag in the other complaints had been blown long before in the pages of our two Medical contempories.

But on turning over the pages of the 'Medical Times and Gazette' of the present week, we can hardly believe our eyes when we find the editor deliberately smashing the image he has himself helped to construct, and wielding his iconoclastic weapons so vigorously and successfully that the ice-bags seem to shrivel into utter insignificance, and the ice itself to melt away like the snow on the hill-top at the approach of the summer dawn. Well may Dr. Chapman exclaim, "*et tu Brute?*" at receiving this unkindly thrust from his former friend and patron, and well may he ruminate on the fickleness of journalistic support, when he sees his pet theories so ruthlessly attacked, and his darling panacea so mercilessly handled.

The 'Medical Times and Gazette' now declares that it cannot understand the scientific principles on which the application of the ice-bags is founded. Now, that is the very predicament we have been in ourselves ever since the ice-bag practice was proposed, but as we do not profess to be able to climb the heights of transcendental therapeutics like our contemporary, we attributed our obtuseness to

some natural defect of apprehension on our own part. But behold! the 'Medical Times and Gazette' is in the same nebulous condition with ourselves, and we can only say, "Why did'nt you say so before?"

True, we were aware that the application of ice to the spine was supposed to lessen the activity of the sympathetic chain of nerves, and thus to dilate the arteries and capillaries distributed to the system, thereby making the circulation more active. But even admitting this hypothesis to be correct, how is it proved that epilepsy really consists in retardation of blood by the action of the vaso-motor parts of the sympathetic system, or is cured by accelerating the circulation in this portion of the nervous textures? And how is it proved that ice possesses this remedial agency? And if ice does possess this property, how comes it that hot water possesses it also, since hot water bags are applied alternately in Dr. Chapman's practice? All these questions we confess ourselves unable to answer, and it is some comfort to us to discover that we are not alone in our perplexity, which is shared by the distinguished editorial staff of our contemporary.

The 'Medical Times and Gazette' now altogether ridicules the theory, and regards the ice-bags and the hot water bags only as modifications of old and well-known external appliances in the shape of warm poultices, cold lotions, &c. We confess that we are very much inclined to be of the same opinion, but we say again, "Dear 'Medical Times and Gazette,' why did'nt you tell us all that before?" Here we have been puzzling our brains for months together to make out the theory of the hot and cold treatment, and on looking with anxious expectation to our contemporary to enlighten our ignorance, he at last turns round upon us and, looking into the ice-bag, like Sir Charles Coldstream looking into the crater of Vesuvius, coolly says, "There is nothing in it," like the knife-grinder in Canning's Sapphics, says, "Story! why bless you, I have none to tell, Sir."

THE CASE OF ROBERT HUNTER.

As we anticipated, the Jury at the Central Criminal Court have acquitted Robert Hunter of the charge of rape preferred against him by a married woman, named Merrick. It is no part of our duty, any more than it is our inclination to endeavour to excite any sympathy for Robert Hunter on professional grounds; but we agree with the Jury, that he is not guilty of the criminal charge preferred against him. We leave to psychologists, and to Old Bailey lawyers to determine the question as to the motives which can induce an apparently respectable married woman, one too who is said to be suffering from the last stage of pulmonary consumption, to come forward in a public court of justice, and describe minutely the story of her own dishonour, when in fact her honour has never been assailed; and we have no doubt that the Jury estimated at their true value the facts, that within an hour after the outrage was said to be perpetrated, the victim returned to the house of the ravisher, gave his infant a shilling, and asked for some embrocation, and on the same day actually wrote him a letter beginning with "Dear Sir," and ending with "Yours obediently." They also probably took into consideration the circumstances that the lady made no complaint whatever to her husband, or to anyone else as to what had happened to her until about a fortnight after the alleged assault, and that at the time of its commission, in broad daylight, and in a house full of people, she made no resistance, and uttered no audible complaint.

We have no intention of entering into details, especially as we publish a report of the trial elsewhere; but we must remark, as a mere scientific point, that the physiological effects described by the prosecutrix as having followed the inhalation, are quite unknown to the Medical world. That Robert Hunter may have discovered some vaporous or gaseous substance, the inhalation of which, while it annihilates all power of resistance, leaves a female in full possession of her consciousness, is perhaps within the limits of possibility; all that we, as Medical writers, can say, is that we know of no such substance, and have some difficulty in believing in its existence.

Having thus expressed an opinion, which we have all along entertained, that Hunter did not commit the crime charged against him, our sympathy is at an end, and we have no desire to join in the shout of triumph raised on his acquittal by the mob collected in the streets of the Old Bailey, and appropriately echoed in the columns of the 'Daily Telegraph.' Strange to say, the 'Times,' which had the distinguished honour of introducing Hunter to this country by publishing in its editorial columns his wonderful powers of curing consumption, does not say a word in favour of its *protégé*, or at least, it had not done so at the time of our writing. It would be really inconsistent in the leading Journal, which sneers at the labours of our native practitioners, if it does not now bestow an eulogium in its leading columns on the transatlantic prodigy who benevolently cures at the rate of only five guineas a month, with an entrance fee of one guinea, a complaint which has hitherto proved, if not incurable, at least somewhat difficult of cure by European physicians.

Since the above was written, the chief daily Journal has devoted a leading article to this case, referring to the prisoner as "a Dr. Hunter." This is rather unkind of the 'Times,' after devoting so many of its valuable pages, no doubt for a valuable consideration, to the promulgation of Dr. Hunter's valuable "discoveries."

REVIEW OF BOOKS.

Clinical Lectures and Reports. By the Medical and Surgical Staff of the London Hospital. Vol. II. 1865. Pp. 415. London: Churchill and Son.

The plan of collecting together and recording the Clinical experience of the staff of a great hospital is an exceedingly good one, and we are glad to find that several of our great Metropolitan establishments have adopted it. We had occasion to notice last year in very favourable terms the appearance of the first volume of Clinical Reports from the London Hospital, and the present book is in every way equal to that which preceded it. The labour and the expense incurred by those who undertake such a work can

be but imperfectly appreciated, except by those who have had similar tasks to perform; and in the present instance the labourers are the more to be commended, because we believe that they neither expect nor receive any reward, except the consciousness of having done their utmost to collect the best materials and to arrange them in the best possible manner.

The contents of this second volume are necessarily of a miscellaneous character, consisting of clinical lectures, original papers or observations, records of cases, reports by advanced students, a list of the more important preparations added to the museum during the past year, statistical reports of Medical and surgical cases during the year 1864, and an index. The illustrations, which consist of lithographs and wood-cuts, are very well executed, and are often of great service in elucidating the subjects described in the text.

It is of course impossible for us to notice all the subjects discussed in the pages before us, but we may select a few which seem to us to possess some points of peculiar interest.

Mr. Curling makes some observations on the treatment of painful cancer of the rectum by establishing an anus in the left loin. He has on a former occasion adduced three cases, in which lumbar colotomy was performed with a view to mitigate many of the distressing symptoms of cancer, and he now publishes a fourth. The operation was so far successful that the patient recovered from its effects, but he sunk soon afterwards, and Mr. Curling considers that the proceeding had been delayed too long. He adds a table of the operations for lumbar colotomy which he has either performed or assisted in, and shows that out of ten cases there were seven recoveries, and he argues that the operation is not so formidable and dangerous as is generally supposed.

Dr. Letheby contributes two papers, one, On Liquid Diffusion in Relation to Physiology and Practical Toxicology, and the other, On the Poisonous Properties of Essence of Mirbane, or Nitro-Benzole. In the former he describes the three methods of investigation pursued by Mr. Graham in studying the diffusion of fluids, one of which is now well known under the name of dialysis; and although this last process is not well calculated to determine the *quantity* of any poison present, it affords a ready means of effecting its *qualitative* examination, while the application of dialysis to the investigation of physiological questions is perhaps still in its infancy. The other paper, on the poisonous properties of nitro-benzole, is a very valuable one, especially at present when this substance is extensively used in commerce for the preparation of the aniline dyes. The oily liquid named nitro-benzole was first obtained in 1834 by Mitscherlich, of Berlin, but in 1844 Dr. Hofman discovered benzole in coal-naphtha, and a cheap and ready method of obtaining nitro-benzole was subsequently discovered; and this substance at last was found to yield the well-known colouring matters by conversion into aniline and subsequent oxidation. Nitro-benzole, however, is a poison, and the immediate object of Dr. Letheby in his paper is to describe some cases of poisoning which have happened with this substance, and to record some experiments made with it upon the lower animals. We have published elsewhere an abstract of these cases taken from the columns of the 'Chemical News.'

Dr. Fraser offers some notes from a Clinical Lecture on Hydrothorax, and some general observations on pleuritic effusions. In this paper the diagnostic marks of pleuritic effusions, as contra-distinguished from cases of consolidation of the lungs, are carefully pointed out, and a number of illustrative cases are related. The same physician makes a few remarks on the statistics of stimulation *versus* depletion, and after some allusion to the chemical questions involved in the discussions raised by the anti-alcoholic party, he proceeds to examine the records of the London Hospital for a series of years, as showing the relation existing between the consumption of alcoholic fluids and the number of cases admitted. The results, although practical and interesting, are not very conclusive, but it appears evident that a steady rise in the employment of stimulants in the treatment of diseases and injuries is still going on; "whatever be the cause," says Dr. Fraser, "we may be assured that the practice is imperative and needful, for it would be a monstrous assumption that a whole staff could be blindly following an objectless routine."

Mr. Hutchinson is, as in the last volume, a large contributor, and his range of subjects is very extensive, as may be inferred from a glance at the title of his papers, including cases of hernia, and on the chief causes of death after hernia-operations; a case of fibro-plastic tumour of the scalp; the diagnosis and treatment of lupus and allied diseases; epithelial cancer; the treatment of cataract; and many others. One of his most interesting papers is on the subject of inherited syphilis, on which Mr. Hutchinson has collected a great mass of information. As a...dication of the hereditary form of the disease, Mr. Hutchinson places great reliance on the appearance of the teeth, which in many cases is sufficiently characteristic, the middle incisors being symmetrically notched. A great number of instances are described in which morbid changes were observed in connexion with hereditary syphilis, and the diagnosis was confirmed by the history of the individuals and of their parents, and by the effects of treatment.

Mr. C. F. Maunder contributes a note on the importance of a differential diagnosis in chancre, and as he is a thorough believer in the duality of the chancrous poison, he insists upon the necessity of arriving at a correct opinion as to the nature of each sore, in order that the treatment, whether with or without mercury, may be regulated accordingly. We may remark, in passing, that the surgical staff of the London Hospital appear to entertain no doubt as to the efficacy of mercury in the treatment of the hard chancre.

Dr. Hughlings Jackson gives some abstracts of lectures on hemiplegia, in which he endeavours to connect the symptoms observed with the nature of the disease, and proposes a classification in accordance with the pathological indications. Thus he describes hemiplegia from apoplexy, from embolism, from syphilis, hysterical hemiplegia, reflex hemiplegia, and pretended hemiplegia; and he also divides the disease into varieties according to its seat, as the corpus striatum and thalamus opticus, the crus cerebri, the pons varolii, the medulla oblongata, and one-half of the spinal cord. On this very difficult subject, Dr. Hughlings Jackson brings to bear a great mass of facts, and a large amount of cautious reasoning.

The above brief notice of some of the subjects touched upon in this volume will give some idea of the number and variety of the topics discussed; and we can only state in conclusion that the whole will ample repay perusal, as being a valuable repertory of facts and experience.

A Guide to the Treatment of Diseases of the Skin; with Suggestions for their Prevention. For the Use of the Student and General Practitioner. Illustrated by Cases. By Thomas Hunt, F.R.C.S., Surgeon to the Western Dispensary for Diseases of the Skin. Eighth Edition. Pp. 260. London: T. Richards. 1865.

The very fact that this work has reached its eighth edition is probably a more emphatic testimony to its merits than any we are able to offer; for what is more complete evidence of the success of a book than its acceptance with the public, and the sale of ten thousand copies? Mr. Hunt is now a veteran practitioner in the department of Dermatology, and he has contributed in no small degree, by his practice and his writings, to simplify the treatment of diseases of the skin. While the leading features of the author's practice have been unaltered, or rather while his views have been strengthened by time and experience, he has introduced a few improvements in arrangement and detail, and a new chapter on ring-worm and other diseases affecting the hairy scalp has been added. Mr. Hunt believes most firmly, as he has ever done, in the constitutional origin of chonic skin diseases, and in the absolute necessity of arsenic as the final remedy, but he prefaces the present edition with a very judicious caution to any patients suffering from skin disease, not to be "so rash as to tamper with arsenical preparations, which ought never to be made

use of excepting under the watchful eye of a Medical practitioner." The illustrative cases adduced by Mr. Hunt are strongly confirmatory of the value of the treatment which he recommends and adopts.

Letts's Diaries for 1866.

These useful works for the year 1866 have just made their appearance, and they are in all respects worthy of the extensive patronage which their predecessors have received at the hands of the public. We understand that their circulation amounts to nearly 300,000, and that it is steadily increasing, and that two prize medals have been awarded to them this year, one in Dublin and the other in Oporto. In addition to the diaries adapted for the use of the general public, there are special ones intended for the Medical Profession, and which contain columns for midwifery and other engagements in which practitioners are concerned in their daily avocations. In point of workmanship, variety of information, and neatness of arrangement, these diaries are in every way to be commended.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

Tuesday, November 7th, 1865.

Dr. Peacock, President.

Mr. Spencer Watson exhibited a specimen from

A CASE OF CROUP IN WHICH TRACHEOTOMY WAS PERFORMED.

A boy, three years old, was attacked by croupy symptoms on September 6 or 7, 1865. He was seen first by Mr. Watson on September 11, when all the symptoms were aggravated in spite of active treatment by antimonials and mercury. On September 13, tracheotomy was performed; and though respiration ceased during the operation, it was restored quickly by having recourse to Silvester's method of artificial inflation. The child rallied, and his breathing became tranquil; but a state of exhaustion ensued, terminating in death thirty-six hours after the operation. On examining the lungs after death, the lower lobes were found to be hepatised, and the croupy membrane extended from the glottis to the ultimate ramifications of the air-tubes. The heart contained pale yellow, and rather firmly adherent coagula.

Mr. Holmes brought forward specimens from, and gave the particulars of, a case of

OPERATION FOR A SOFTENED FIBROID TUMOUR OF THE UTERUS,

mistake for ovarian disease. Mrs. S., married, two children, aged twenty-nine, was a patient in St. George's Hospital in the summer of 1865, in consequence of a tumour which filled up the whole abdomen, and which was producing rapid emaciation, increasing dyspnœa, occasionally recurring in paroxysms, and threatening even to prove fatal. She had been previously a patient in St. George's Hospital under the care of Dr. R. Lee, and again under Mr. Brodhurst, and she had been for some time in the Samaritan Hospital under Mr. Spencer Wells in the early part of the year 1864. In Dr. Lee's opinion, the tumour was ovarian, but closely adherent to the uterus. Under Mr. Wells the disease had been diagnosed as being due to the presence of three fibroid tumours of the uterus. She was never known to have had any uterine hæmorrhage. The tumour was of four years' known duration, and was accidentally discovered by herself by touch. At first time there were no symptoms connected with the disease. Latterly, however, she had been losing flesh, and strength rapidly, and was urgently desirous that some operation should be done if possible. The whole of the anterior part of the abdomen was dull to percussion, but there was slight resonance in either flank; motion of the body had no apparent effect on the mass. There was doubtful fluctuation in most parts. Examination by the vagina and by the rectum showed that the pelvis was filled by the mass. The os uteri was natural. The cervix could be felt, but not the body, and it was impossible to discover whether or no the uterus moved on the tumour. In the month of July, as the dyspnœa had become very urgent, paracentesis was performed by Mr. Holmes; only very little fluid (about half a pint) escaped through the trocar, it was almost colourless, and of a gelatinous consistence, but after the withdrawal of the instrument, as much as a gallon of the same kind of fluid exuded slowly in the space of about twenty-four hours. This gave her great temporary relief; but the tumour again increased, and one night the House-Surgeon was called suddenly to her, as she was thought to be dying of dyspnœa; this was in the month of August, during Mr. Holmes's absence from town. Paracentesis was again performed, and the result was reported as being almost exactly the same as on the previous occasion, that is to say, very slight flow at the time, followed by a copious exudation with great relief to the breathing. On Mr. Holmes's return in September, the woman was anxious that the question should be settled. She had become greatly emaciated, and the pulse was very small and weak. She knew that she had not long to live, and was very desirous of taking the chance of an operation, if it was judged to be justifiable. She had, however, been informed of Mr. Spencer Wells's diagnosis, and was aware that an attempt to remove the tumour, if uterine, would prove fatal. A careful examination was made by Dr. Lee and by the surgeons of the Hospital, and the idea of its being a case of fibroid tumour was rejected, mainly on account of the absence of uterine symptoms, the great extent of the tumour, and the large quantity of fluid evacuated from it. Dr. Lee only took part in the consultation so far as the diagnosis was concerned. The surgeons of the Hospital agreed that it was justifiable to attempt an operation under all the circumstances, and this was accordingly done on September 20. Before operating Mr. Holmes explained to those who were present, as he had previously to the patient, that the operation must be looked on as exploratory only, as his opinion was almost equally divided between ovarian tumour and the fibro-cystic degeneration of the uterus which so closely simulates it, and of which illustrations and cases are found in the Transactions of this Society (vol. xiv., pp. 198, 204), and of which a specimen exists in the museum of St. George's Hospital. However, on cutting down upon the tumour, these doubts were no longer entertained; it looked so exactly like an ovarian tumour that none of the surgeons present doubted that it was so. There were a good many very firm adhesions in front to the abdominal walls and to the omentum, which was spread over its anterior surface, and the vessels in which were of very large size, giving rise to pretty copious hæmorrhage. In some parts it was necessary to use the knife. When the anterior part of the tumour had been cleared as far as possible, the trocar was introduced, but no fluid would flow through, until by squeezing and cutting freely into the tumour its bulk had been so far diminished that it seemed possible to extract it from the wound, which had now been extended to the whole length of the abdomen. The adhesions, however, were universal, and were of extreme density in the neighbourhood of the liver and spleen, necessitating the cautious use of the knife here again. When these had been overcome, the tumour was found to be still more firmly adherent behind to the mesentery, and almost incorporated with the small intestines. The patient had now become excessively exhausted, and in separating as rapidly as possible the tumour from its posterior connections, the small intestine was torn. This, it is believed, took place from the weight of the tumour. The peduncle was of small size, about the circumference of the thumb. A piece of stout wire was twisted round it. The patient rallied after the operation, but after the first rise in the pulse she suddenly sank, as though from internal hæmorrhage, and died the same afternoon, about four hours after the operation. The main tumour which had been removed was of very large size, and weighed above 11 lbs., even after it had been drained of fluid. Its texture was spongy or reticulated, without any actual cysts, but with very large spaces in some parts between its meshes of fibres. It appeared to have resulted

from the softening of an ordinary fibroid tumour. It was attached by the small stalk above mentioned (which was not above 1½ in. in length) to the top of the fundus uteri. The walls of the uterus were full of fibroid tumours of various sizes, the whole forming a mass about as large as a cocoa-nut. This mass formed the second tumour spoken of in the above description of the case. A third tumour, about the shape and size of the spleen, was attached to the fundus uteri on the right side by a pedicle, and was lying in the right iliac fossa. The cavity of the uterus was elongated, measuring from os to fundus about five inches. The peritoneal cavity contained a large quantity of blood, and this hæmorrhage seemed to have been the proximate cause of death.

Mr. HOLMES then made the following remarks:—The above case is presented to the Society as one in which there were unusual difficulties, leading to an error in diagnosis which was not discovered even when the tumour was exposed to the sight. There was, on the one hand, the clear history of a careful diagnosis by so experienced a surgeon as Mr. Spencer Wells; but, without any discredit being cast on that diagnosis, the main tumour might still have been ovarian. Of the co-existence of ovarian cysts of large size with fibroid tumours of the uterus, an example is published in the last volume of these 'Transactions.' So that it was quite possible that the woman, when under Mr. Wells's care migh have presented no visible indication of the ovarian cyst which had grown to such large proportions afterwards. At the time of her last stay in St. George's Hospital, the main tumour masked everything else; and if two of the uterine tumours (supposing them to exist) had been covered and concealed by the larger mass which filled the abdomen. why not the third? Again, the large size and rapid growth of the tumour was much more like ovarian than uterine disease. The great quantity of fluid which the growth yielded on paracentesis was another very deceptive feature in the case, and so was the absence of uterine hæmorrhage and of any perceptible uterine displacement. On the whole, it may be said that no sufficient elements for an exact diagnosis existed at the date of her last stay in St. George's Hospital without an exploratory incision. The operation, however, was only undertaken as an exploratory one; and here one of the most unfortunate peculiarities of the case comes in—viz., that the appearance of the tumour and its uniform semi-fluid consistence were so deceptive that, even after it was exposed, no one doubted that it was an ovarian cyst. This led to persevering attempts at its extraction, and these attempts were necessarily attended with great embarrassment on account of the extensive adhesion of the tumour and the impossibility of lessening its bulk without much violence and consequent loss of blood. It had been found in the early stage of the operation that the lower part was free and pedunculated, and this was an additional encouragement for persisting with the operation. But the abdomen had to be laid open from one end to the other, and the patient was greatly exhausted before the hand could be passed round the upper part of the tumour. When this had been effected, the most difficult part of the operation commenced—viz., the separation of the tumour from its posterior connections. It was in doing this, necessarily in much haste, for the patient's condition was very critical, that the intestine was lacerated; and thus the fatal event was made certain. But even without this it is most improbable that she would have survived long—in fact, she appeared actually to die from hæmorrhage rather than from extravasation of the contents of the intestine. The case is put on record as an interesting example of the great difficulties which surround diagnosis in such cases, and also of the formidable nature of the connections which solid tumours form when growing among the abdominal viscera.

Mr. BRYANT remarked on the interest of the case brought before the Society, and alluded to a preparation which had recently come under his notice at Guy's Hospital which bore upon it, as well as a preparation brought before the notice of the Society by Mr. Wells some time since. He was quite unacquainted with the history of the preparation which he had examined, but he had seen enough to satisfy himself that it was one of cystic disease of the uterine structure, for the uterus was evidently much enlarged by the development of cysts within its walls. These cysts were of great size, and contained fluid said to have been like the fluid of an ovarian dropsy. The tumour had a smooth outline, and doubtless, before death, had simulated that of an ovarian dropsy. The external aspect of the tumour was, however, very different from that exhibited in ovarian disease, for it had a fleshy, fibrous aspect, and would necessarily have suggested to a surgeon during gastrotomy the question of its ovarian nature, and the probability of its being a tumour. Mr. Bryant was unable to say whether the uterine sound had been employed in the case to which he had alluded; but if it had, the cavity of the uterus would have been found much enlarged. A full account of this preparation, with its history, would doubtless be brought under the notice of the Society during the session.

Dr. GRAILY HEWITT asked if the uterine sound had been used?

Mr. HOLMES replied that it had not. It is hardly likely, considering the pressure to which all the parts were subjected by the superincumbent mass, that it would have been possible to pass this instrument to the bottom of the enlarged uterine cavity. Still it may be a matter of regret that it was not used.

TWO CASES OF AMPUTATION AT THE HIP.

Mr. HOLMES exhibited the femora in two cases in which he had recently performed amputation at the hip, with success,—at least, as far as recovery from the operation went. The first was that of a boy, between six and seven years of age, who had been originally admitted into the Hospital for Sick Children, on account of long standing disease of the hip. For this he had been under treatment in various institutions for long periods of time, but was not benefited. Finally, Mr. Holmes determined to try the effect of excision of the head of the femur. The acetabulum was found but slightly affected, but the femur was very soft, almost rotten; and though a good deal of it was removed, it was found impossible to expose more healthy bone. The boy went on pretty well at first, then alarming cerebral symptoms came on. He had fits of screaming, followed by very severe convulsions, in which it was thought probable that he would die. He partially recovered under the influence of counter-irritation, the head being shaved; but the screaming fits still continued. The limb could not well be maintained in position, and the upper end of the femur protruded, and became dead. A sequestrum about two inches long was drawn out with the fingers. Still the screaming fits did not cease, and he suffered greatly from pain, coming on in nocturnal exacerbations. An abscess now formed near the knee, and the probe passed down into softened bone, in the lower part of the femur. It seemed possible that the irritation of the diseased femur was keeping up the cerebral disturbance, and as the limb was clearly useless, it was decided to give the child the chance of life afforded by its removal. This was done on September 6. The aorta being held by Mr. Marsh, of St. Bartholomew's Hospital, by manual pressure, no blood was lost. A large anterior flap was cut from the skin towards the interior; then the connections between the ilium and femur were severed, and the posterior flap cut from within outwards. The vessels were tied, and the acetabulum, which was somewhat softened, was freely gouged out. At the position of the old wound, the cicatrix was so adherent to the os innominatum that it was imposible to bring fresh edges together. Much of the wound healed by first intention, and the child greatly improved in health and general condition; the fits of screaming ceased, and he passed tranquil nights. There was still a little discharge from the position of the old wound when he was sent to the Margate Infirmary, about a month after the operation. Here, however, after a short time, the cerebral symptoms recurred, and at the time of the exhibition of this specimen, he was reported to be sinking from the brain disease. The specimen shown to the Society (with a coloured drawing) exhibited the results of osteo-myelitis, or acute and total disorganising inflammation of the whole shaft, which was separated from the epiphysis, and lying

ad, and in most parts loose in a periosteal case of new me—the epiphysis and the encasing bone being very scular. The medullary cavity was full of pus, and the sue of the dead bone was also infiltrated with pus. The se was brought forward as a good example of this disease, d also as bearing on the question of the feasibility of nputation in chronic disease of the hip, if excision has iled. There are, in Mr. Holmes's opinion, many cases of p-disease in which the local affection is the only disease der which the patient labours—which are in no more ict sense constitutional diseases than the common ronic (so-called "strumous") disease of the knee. This ter disease is every day treated successfully by excision amputation—why not disease of the hip? The answer, course is, that in disease of the knee the femur can be rided above the part affected, which is impossible in the e of the ilium. It is well known, however, that in a tain proportion of cases of hip-disease (as in this) the ease is, if not limited to the femur, at any rate far more tensive in it than in the acetabulum. If in such a case cision has been performed and has failed, so that the tient can never hope for a useful limb, yet seems likely survive for a long period, is it not more reasonable to ve him the chance of an operation than to leave him to tain death? The operation in a child, where the aorta n be thoroughly commanded, need not be a bloody one; d the acetabulum is so completely exposed that it can removed to any extent which may be judged necessary. en if perforated, the whole might readily be taken away, thout in all probability much increasing the risk of the eration. The second case was that of a woman, aged rty-six, a patient in St. George's Hospital, who had ce submitted to the removal of a large tumour, of the urrent fibroid variety, situated at the back of the thigh. the time of the first operation, in the early part of the sent year, the tumour, though of large size, was comatively superficial and easily removed. This operation s performed by Mr. Tatum. She left the house with wound healed, and enjoyed an interval of about three nths' health. The tumour had been pronounced to be he recurrent fibroid variety at the time of the operation, er microscopic examination by Dr. Dickinson. It re-red beneath the scar, and grew rapidly, with much oting pain down the course of the sciatic nerve. The ond operation was performed on June 29 by Mr. Holmes. e mass was ill-defined, infiltrated among the muscles of limb, and extended from the neighbourhood of the hanter to the popliteal space. A great deal of muscular structure was removed, including about inches of the entire circumference of the biceps cle, and the sciatic nerve had to be carefully dis-d from the mass, which adhered to, and appa-y infiltrated, its sheath. The deep parts of the id, however, appeared still infiltrated with the same oid deposit, though it was followed round the femur to the inner side of the limb. The operation was ourse long-continued and bloody, and she recovered it but slowly. Lint, saturated in a solution of iate of copper, was stuffed into the wound, so as, if ble, to induce sloughing of the fragments left behind e tumour. The only noticeable symptoms in her con-cence were the persistence of pain in the course of the c nerve, and a very severe attack of secondary hæmor-, which occurred on July 23, without any very ob-cause. This was so severe that it was decided to am-e the limb if it should recur. However, local measures ed it. The tumour, however, soon began to fungate f the wound, and to grow in the deeper parts, accom-d by exhausting discharge and by sloughing of the ting portion. As her health was rapidly sinking, it lecided to give her the last chance of amputation at oint. The tumour had spread so far upwards that a ould only be obtained from the front; and even here uscles were much infiltrated on the inner side, so that aps had to be formed chiefly of skin. The operation performed on September 14. Mr. Lister's tourniquet pplied on the abdominal aorta; but the instrument omewhat too large, and did not entirely control the hæmorrhage. Still, it very much checked it; and by commanding any bleeding orifices with sponges and finger pressure any great loss of blood was avoided. The anterior flap was cut from the skin inwards, the muscles not being divided till close to the groin, so as to avoid all diseased tissue. The knife was brought straight out at the back, little or no flap being available in the buttock. She was at first in great danger of sinking, and suffered severely from vomiting—the result of chloroform. Her strength was supported by nutrient enemata as long as possible; but then a slight attack of diarrhœa threatened to complete her exhaustion. From this, however, she rallied; much of the stump united by first intention, and it never required any dressing. The silver sutures were left in for a fortnight, when the adhesion of the wound was tolerably complete. She left the Hospital on October 24, to go to a neighbouring charitable institution, where she still remains. Her general health is good, but she suffers severely from pain in the stump, though the latter is very well formed, and there is no present evidence of any return of the disease.

These two cases seemed of some interest as examples of recovery from amputation at the hip performed under very unfavourable circumstances on patients much exhausted by previous disease and operation. This success Mr. Holmes attributed mainly to the aortic pressure, by which excessive hæmorrhage was avoided.

OBITUARY.

DR. J. A. EASTON,
Professor of Materia Medica in the University of Glasgow.

This distinguished physician and worthy man died suddenly at his residence in Blythswood square on the 12th inst. Fully two years ago the doctor was assailed by a sudden illness, which for a time wore a very serious aspect; but he speedily recovered and resumed the full discharge of his extensive professional duties. In August last, however, he had a slight paralytic attack in the face, from which he also came round quickly, and resumed his work; but it was apparent to those who knew him intimately that the attack had left traces of weakness behind, and henceforth his family experienced some uneasiness regarding him. On Sunday morning he was up about eight o'clock, and went into a plunge bath as usual, but on retiring from it he felt ill and went to bed. Rapidly becoming worse, Medical aid was called in, and Drs. Fleming and Coats were in attendance without loss of time; but their aid was of no avail. It was evident to these gentlemen that their friend was suffering under a fatal attack of apoplexy, from which he breathed his last at eleven o'clock.

Dr. Easton, who had completed his fifty-eighth year, was born in India, in which, we believe, his father belonged to the Medical service. While still a boy, he was sent to a relative in this city for his education, and in due course entered the University. He chose the Medical Profession, and was licensed by the faculty in 1828. At first his practice was very limited, as it is in the case of all young Medical men who have to depend entirely upon their own ability and exertions for advancement in the world. His first public appointment was that of a district surgeon, in which capacity he laboured amongst the poor with singular zeal and success. Meanwhile his private practice was extending; he was becoming known as an earnest, accomplished, and experienced physician, for he had the degree of M.D. in 1836; and when the office of surgeon of the police force became vacant in April, 1840, he was selected out of ten candidates for the appointment. He filled this situation till October, 1855, when he resigned the part of it which involved the attendance upon cases of accident in the police office; but he retained the office of surgeon to the force till November, 1859, when he resigned it on account of the great extension of his practice, especially amongst the highest class in the community, which had now been added to the duties of his professional chair.

He was succeeded in the police appointment by Dr. M'Gill, who had for some years previously been his assistant. In the meanwhile he filled appointments in the Medical institutions in the city, and contributed important papers to the Medical periodicals in this and other cities. He officiated for some years as Lecturer upon Materia Medica in the Andersonian Institution, and when the Professorship of Materia Medica in the University became vacant in 1855, he was appointed to the chair by the Government.

Dr. Easton's professional life has been characterised by a well-balanced application to both the scientific and the practical, keeping pace with all that was promulgated by the best authors, whether British or Foreign, on the numerous branches of Medical science. As Professor of Materia Medica his attention was, of course, more especially directed to the wide field of elementary and compound agents which are used in the treatment of disease. The knowledge essential to the successful cultivation and teaching of so vast a subject required an intimate acquaintance with chemistry, botany, natural history, pharmacy, and therapeutics—in all of which he was deeply and accurately learned. As a teacher he had many elements of popularity. He wrote with ease and classical elegance; his illustrations were appropriate and ingenious; and though at times his style and rhetoric may have been rather ornate for a severe and fastidious taste, he never failed to convey to the youthful mind, in a clear and perspicuous manner, a knowledge of whatever subject was under consideration. His kind and genial manner, and the warm interest he took in his students, made him at all times a great favourite among them, and to the confidence with which he inspired them, as a physician and a friend, he owed much of that practice as a consulting physician he was so rapidly obtaining.

During the time he held the appointment of Police-Surgeon in this populous city, his opinion and evidence were sought in all the important cases which occurred involving questions of legal Medicine. In this difficult and delicate branch of his Profession he soon acquired a well-deserved fame.—'Glasgow Herald.'

WILLIAM JEAFFRESON, Esq., F.R.C.S.

Those of our readers whose student-life and early professional interests were contemporaneous with the mature fame of men whose names form a portion of the history of Medicine and surgery of the early part of this century, will hear with regret the death of Mr. William Jeaffreson, of Framlingham, Suffolk, who died on the 8th instant, at the advanced age of seventy-five. Having received his early education at the Bury Grammar School, he became a member of the Royal College of Surgeons in 1812, after studying medicine and surgery for three years at the combined school of Guy's and St. Thomas's Hospitals, to which the name of Sir Astley Cooper attracted so many students. To those acquainted with the history of ovariotomy Mr. Jeaffreson is known as the originator of the minor operation for the removal of ovarian cysts, which he performed several times with success. The reports of these cases were recorded in the "Transactions of the Provincial Medical and Surgical Association," 1836. Although Mr. Jeaffreson was successful in lithotomy, with which operation practice in the eastern counties made him familiar, he at once saw the benefits, in many cases, to be derived from the proper employment of the lithotrite, at a time when that instrument, in the hands of Mr. Costello, was producing results admitting of, and receiving, very various judgments from the Profession. He was the first provincial surgeon who, in the country, performed lithotrity; which operation, by a proper selection of cases, was uniformly successful in his hands, with one exception only, in which case, with commendable candour, he made public the failure and its causes. In consideration of his professional services, he was in 1844 made an Honorary Fellow by the Council of the Royal College of Surgeons. But few of his contemporaries remain, who were in the habit of yearly meeting him at the annual elections and dinner of the College, where he was always cordially received as representing the advance made in provincial surgery in the present century. In his own neighbourhood Mr. Jeaffreson was highly esteemed; and although he had for several years retired from the active duties of life, many will again feel their loss of the surgeon in regretting the death of the friend. In 1848 he joined the Council of the Provincial Medical and Surgical Association, and subsequently acted as the President of the Eastern Branch of that Association on the occasion of their meeting at Framlingham.—'Lancet.'

PARISIAN MEDICAL NEWS.

DISLOCATION OF THE FEMUR ON THE PUBES.

The following remarks are by Dr. Morillon, of Pont Sainte-Maxence, (Oise):—On the 25th of August of the present year, a workman employed in a tan-yard at Pont Sainte-Maxence, was engaged in occupations which compelled him to adopt a squatting attitude, when a bag filled with oak-bark fell upon his back from a height of about eighteen or twenty feet. The man was immediately relieved by his companions from the superincumbent weight, but was unable to rise alone, and was carried to his home, where I was immediately summoned.

The following was the condition in which I found him:—

The left inferior extremity presented a shortening, at least apparent, of two and a half or three inches, the heel resting on the upper part of the malleolus of the uninjured leg, and the foot pointing directly outwards; the thigh was extended, rotated outwardly, and in abduction. The corresponding buttock was flattened, and the inferior fold less marked than usual; the prominence due to the trochanter major was replaced by a deep cavity large enough to admit the closed hand; in addition, the head of the bone was plainly felt in the groin, between the crural artery on the inner side, Poupart's ligament above, the inferior spinous process of the ilium outwardly, and at the back the edge of the acetabulum.

These signs obviously pointed to the existence of the dislocation upwards and forwards on the pubes, which Mr. Malgaigne designates as the *ilio-pubic*.

Being summoned so soon after the occurrence of the accident, I concluded that I could easily reduce the displacement, without the assistance of chloroform, by the method recommended by Desault and Boyer. The patient was laid on a bed, around which the attendants could easily move; a cloth was securely fixed above the ankle, and while the assistants applied vigorous horizontal traction to this part of the limb, the pelvis being at the same time secured by proper means of counter-extension, I endeavoured to rotate the thigh inwards, and, agreeably to the precepts of Dupuytren, to combine this movement with some degree of flexion. These attempts entirely failed in accomplishing the purpose. I then had recourse to chloroform, no less than one ounce of which was inhaled before a satisfactory state of anæsthesia could be induced. Its action on the system was of course closely watched, and all muscular resistance having at last been conquered, I repeated my former efforts, but without greater success.

Reflecting on the various procedures adopted by modern surgeons for the reduction of dislocation of the thigh, which consist in general in flexion combined in succession with direct pressure, rotation inwards, abduction, and slight traction, I was preparing after a slight interval of repose to apply these measures, when it suddenly occurred to me to try a plan which I believe has never yet been employed.

The patient having recovered consciousness, I caused him to be supported in a standing attitude by several vigorous men, and in such a position that the uninjured limb alone rested on the ground, the displaced extremity hanging in an inert manner. I then embraced the thigh with both arms like the trunk of a tree, and acting with all my strength, increased by the weight of my body, exercised vertical traction. Feeling that the head yielded to the efforts, I gently rotated the thigh inwards, and to

peculiar snap indicative of reduction was immediately perceptible. The man was replaced in bed, both legs were secured to each other in order to prevent all motion in the injured joint, and on the 25th of September the patient was enabled to walk with the assistance of crutches.

In his important treatise on dislocation, Mr. Malgaigne, describing the ilio-pubic luxation, adverts, amongst the various methods of reduction used in the days of Hippocrates, to one in which the patient being placed crosswise on the highest step of a vertical ladder, the healthy limb was securely held on one side, while to the other was attached a vase filled with water, or a basket weighted with stones. This procedure, as will be seen on slight reflection, presents some distant analogy with that adopted in the case I have related; but in my procedure the surgeon does not employ a blind power, he can vary the direction and intensity of his efforts, and combine traction with rotation, thus following and directing the head of the bone in its return to its proper situation. In this respect the method resorted to by me differs materially from the vertical extension described by the Father of Medicine, and as I have failed in discovering any mention of it in the many authors I have consulted, I have thought it expedient to trouble you with the present communication.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College, at a meeting of the Court of Examiners, on the 6th inst.:—James Henry Wardle, L.R.C.P. and L.R.C.S. Ed., Stalybridge; Isaac Taylor, York; Richard Bottomley Lowell, Manchester; James Hopkins Walters, Barnstaple; Richard Girdleson Lubbock, Norwich; Francis Manley Soldero Sims, Colchester; Henry Cribb, jun., Bishops Stortford; Frederic William Hodder, M.B., Toronto, Canada West; William Leigh, L.R.C.P., Chiswick; Charles Bailey Greenfield, M.B., Edin., Cheltenham; Frederick Sydney Coombe, Trafalgar square, Chelsea; Charles Jas. Harris, L.S.A., King William street, Strand; John Edward Montague Finch, B.A., Cantab., Fisherton, Salisbury; David Gregory Tuckwell, Oxford; James Mare Taylor, L.S.A., Tanley, Staffordshire; William Roberts, Retford, Notts; Nicholas Hall, Salford, Manchester; and David Anderson Coxey, M.D. Edin., Turnham green.

It is stated that out of the sixty-nine candidates who offered themselves for examination, only seven were returned back to their studies for the usual period of six months.

NAVAL SURGEONS.—At a meeting of the Court of Examiners of the Royal College of Surgeons, on the 16th inst., the following gentlemen passed their examinations as Naval Surgeons:—Rinso Robert Siccama, L.S.A., of the Royal Naval Hospital, Haslar, diploma of membership of the College dated July 27, 1857; Samuel Bamfield, L.S.A., of H.M.S. 'St. George,' Portland, diploma of membership of the College dated July 18, 1859; Charles John Cornell, L.S.A., of H.M.S. 'Wellesley,' Chatham, diploma of membership of the College dated July 19, 1859; Henry Packard, L.R.C.P., of the same ship, diploma of membership of the College dated December 6, 1859; John Sampson Levis, M.D., Queen's University, Ireland, of the Royal Naval Hospital, Haslar, diploma of membership of the College dated November 15, 1860; and Robert Nelson, L.R.F.P. and Surgs., Glasgow, diploma of membership of the College dated June 12, 1860, Royal Naval Hospital, Haslar.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, November 16, 1865:—Richard John Lupton, Stanhope street, Hampstead road; Geo. Rendle, 40 Newington causeway, S.E.

NORTH STAFFORDSHIRE MEDICAL SOCIETY.—The annual meeting of this Society was held at Stoke on the 16th inst. Samuel Goddard, Esq. (the retiring president), having read his address, the election of officers for the ensuing year took place, and the following was the result:—President—W. Haslam Davis, Esq. Treasurer—James Yates, Esq. (re-elected). Honorary Secretary—Ralph Goodall, Esq. (re-elected). Committee—Dr. Arlidge, John Alcock, Esq., Dr. Cream (re-elected), C. Orton, Esq. (re-elected), and Dr. Taylor (re-elected). From the Report of the Secretary read and adopted on the occasion, we find that the financial condition of the society is highly gratifying; that there have been five meetings during the past year, at which able and practical papers have been read, and the discussions consequent on the same most interesting and instructive; indeed practical usefulness seems to characterise all the proceedings of this society. The consideration of Medical etiquette also forms a distinguishing feature thereof with marked benefit. At this meeting it was agreed that the Secretary—"Do convene a meeting by circular for the 14th proximo, at the North Staffordshire Hotel, Stoke-upon-Trent, of all the Medical practitioners of the district, to consider the present condition of the 'Club System', with the view to its better administration."

HOMŒOPATHY AND THE CATTLE PLAGUE.—We have authority for stating that the despatches received at the Foreign Office from the Dutch Minister of the Interior announce that the alleged applications of homœopathy to the treatment of cattle affected with the rinderpest in Holland have been much exaggerated; that the statements as to their great success are unfounded, and that there are not now any cattle in Holland being treated "homœopathically" under official sanction. We believe that the total number on which these rumours were based amounted to eighty out of the many thousand cattle affected. With reference to the employment of that treatment in this country, we learn that a physician and veterinarian practising homœopathy, and in whom confidence is reposed by the friends of that practice were despatched to Norwich, where the plague is committing ravages, with a view to undertaking the preventive and curative treatment of the cattle. We learn on good authority that they have rejected all but eight out of a number of cattle offered to them; and our advices, two or three days since, stated that, in the treatment of these, there was complete want of success. We may add that the statement put forward that the Cattle Plague Commission have refused facilities to homœopaths to test their treatment are entirely unfounded. Lord Bury was completely misinformed in this matter. The Commission afford the fullest opportunity to these gentlemen. It is to be regretted that statements so exaggerated and calculated to mislead on both the above subjects should have been hitherto persistently advanced.—'Lancet.'

ILLEGAL DETENTION OF A LUNATIC.—Two persons named Ayres and Harris have been committed by the county magistrates at Oxford for the illegal detention and cruel treatment of a lunatic at Marston in that county.

THE CATTLE PLAGUE.—The Privy Council has published a consolidated order—superseding all previous orders—on the cattle plague. This document gives power to local authorities to appoint inspectors who may order premises to be disinfected and cleansed. They may also order that any animal they suspect of being diseased shall be segregated, and in case of refusal on the part of the owner they may order the animal to be killed. Cattle owners are not to remove diseased cattle by rail, or road, or otherwise, under a penalty. Local authorities may close all the fairs and markets of a district, and where the local authorities of a district adjoining that where the fairs are closed refuse to close the fairs in their district also, they may be set aside, and the orders of the first-named local authorities will be sufficient to close the fairs in the second district also, upon its being shown that there is danger of the infection spreading. No cattle may be moved without a licence from other parts of the country into districts which are closed. In London every animal brought to market must be slaughtered within a specified time. The order is to be in force till the first of March next.

PHARAOH'S SERPENTS.—A meeting of the Pharmaceutical Society was held a few days ago at Edinburgh, and in the course of the proceedings the following communication

was read from Dr. Stevenson Macadam on the poisonous ingredients in Pharaoh's serpents:—"The chemical toy, which is now sold largely in many shops in this city, at prices ranging from 3d. to 1s. each, is composed of a highly dangerous and poisonous substance, called the sulpho-cyanide of mercury. The material is a double-headed poisoned arrow, for it contains two poisonous ingredients—viz., mercury and sulpho-cyanic acid, either of which will kill. Experiments have been made by me upon the lower animals, and I have found that one half of a 6d. Pharaoh's serpent is sufficient to poison a large-sized rabbit in an hour and three quarters. A less dose also destroys life, but takes longer to do so. The toy, therefore, is much too deadly to be regarded as merely amusing; and seeing that it can be purchased by every schoolboy, and brought home to the nursery, it is rather alarming to think that there is enough of poison in one of the serpents to destroy the lives of several children. And the more so that the so-called Pharaoh's serpent is covered with bright tinfoil, and much resembles in outward appearance a piece of chocolate or a comfit. I hope that the rage for the Pharaoh's serpents will die out in Edinburgh without any disastrous consequences, though such have occurred in other places; but it is certainly an anomaly in the law of the kingdom that a grain of arsenic cannot be purchased except under proper restrictions, and that such articles as Pharaoh's serpents, containing as deadly a poison, may be sold in any quantity, and be purchased by any schoolboy or child."

STREET ACCIDENTS.—PRESENTMENT BY THE GRAND JURY.—On Wednesday the grand jury, on the completion of the business before them for the present sessions, came into court and made the following presentment through their foreman, Mr. Furze:—"The case of William Belcher, in which we have returned a true bill for feloniously killing and slaying a poor old woman while crossing a street, induces us to represent the extreme danger to foot passengers in London by the fast and reckless driving of tradesmen's carts, vans, cabs, omnibuses, &c., and the urgent necessity of some greater security and facility to foot passengers than now exist. We do not advocate so much increased severity of punishment as preventive measures by municipal and police ordinance; and we do most earnestly deprecate the prevailing idea of drivers of public and private vehicles generally, that foot passengers are allowed to cross the streets by sufferance only, and not by right.—THOS. H. FURSE, Foreman, &c." The reading of the document by the Deputy Clerk of Arraigns elicited a murmur of approbation in court; and Mr. Justice Byles, addressing the grand jury, said that the portion of the country included within the extensive jurisdiction of that court was very much indebted to them for the services they had performed. With respect to their presentment the metropolis was more especially indebted to them. The last session a cabman was tried and convicted of manslaughter before him; and it was a lamentable fact that such cases were occurring every day. He agreed with them that the case to which they referred was a signal instance of danger to foot passengers, and he trusted their presentment would receive due weight in the proper quarter.

THE 'Lancet' Commissioner on the Bermondsey Union, in speaking of the reports of the visiting committee of that workhouse, animadverts on the extraordinary ignorance of spelling exhibited by the guardians who constitute the committee. One signs his name to a statement that the condition of the house is "verey good;" another pronounces it to be "verry good;" a third testifies that all "appeors quiet;" and a fourth, in reply to the printed question, "Are the lunatics quiet?" "Yes, they har."

THE COLLEGE FELLOWSHIP.—During the past few days there have been examinations going on at the College of Surgeons for the Fellowship of the College, when ten candidates presented themselves—viz., four seniors and six juniors. The following were the questions submitted to the candidates on the 21st inst.:—*Anatomy and Physiology.*—1. Give an account of the structure of voluntary and of involuntary muscular tissue. 2. Describe the cartilages, ligaments, muscles, and nerves of the larynx, and their several uses in reference to the production and modulation of the voice. 3. Describe all the varieties in the course of vessels to be remembered in performing the operation of tracheotomy. 4. Describe the ganglia found about the head and face, their situations and relations; the sources whence they derive motor, sensitive, and sympathetic branches. 5. Give an account of the form, the boundaries and the contents of the axilla, and the relations the contents hold to each other. 6. State the relative position of the duodenum to all the adjacent parts; describe the anatomical structure of the duodenum; enumerate the various secretions entering it, and explain their physiological purposes. On November 23:—*Pathology and Surgery.*—What are the causes of hæmaturia? State the reasons which would induce you to believe that the blood came from the kidney, the bladder, the prostate gland, or the urethra, and give the treatment you would adopt in each case. 2. Enumerate the diseases of the female breast, and give the constitutional and local treatment you would pursue in each disease. 3. How would you treat fracture of the pelvis complicated with laceration of the membranous portion of the urethra? State the symptoms which may arise, and the difficulties you may have to encounter in the treatment of the case. 4. In what case of injury or disease would you puncture the urinary bladder? Name the part of the bladder you would prefer to open, and your reasons for selecting that part. 5. What are the diseases of the prostate gland? Describe the symptoms and treatment of each disease, and the changes which they produce in the urinary organs generally. 6. Describe the symptoms of an urgent case of strangulated intestinal hernia of a few hours' duration; and of an intestinal hernia of long standing which has become strangulated. Explain the means you would employ for the reduction of the intestine in each case, and the treatment, both constitutional and local, you would pursue.

DUBLIN OBSTETRICAL SOCIETY.—The first meeting of the twenty-eighth annual session of the above Society was held on the evening of Saturday, the 18th inst., in the Pillar Room of the building known as the "Rotundo," adjoining and in connection with the Dublin Lying-in Hospital. There was a very large attendance of members and visitors. The chair was taken at half-past 8 o'clock by Dr. Churchill, President of the Society. The report having been read, and a ballot having been opened for the election of officers, the President delivered a most interesting and instructive address, giving a comprehensive sketch of the progress of obstetrical science during the last thirty years; a progress which the establishment of the Dublin Obstetrical Society, originated by Dr. Evory Kennedy during his Mastership of the Hospital, and the subsequent formation of the kindred Societies of London and Edinburgh, has largely contributed to promote. The ballot having closed, Dr. Churchill declared the following officers duly elected for the ensuing year.—*President*: Dr. M'Clintock; *Vice-Presidents*: Drs. Hardy and Johnstone; *Treasurer*: Dr. Halahan; *Secretary*: Dr. Kidd; *Committee*: Drs. J. Byrne, Churchill, Cronyn, Denham, and J. R. Kirkpatrick. The new President having taken the Chair, a vote of thanks to Dr. Churchill, proposed by Dr. Beatty, President of the King and Queen's College of Physicians, and seconded by Dr. Sawyer, was passed unanimously.

THE NEW CHEMICAL PROFESSORSHIP AT OXFORD.—Sir Benjamin Brodie, Bart., M.A., has been appointed Waynflete Professor of Chemistry at Oxford. This appointment will render vacant the Aldrichian Professorship of Chemistry, which will not be filled up now. The friends of science at Oxford are still few in number, and even these we are afraid, do not put out all their strength. From the proceedings of a recent meeting to consider a proposed extension of the University, it would appear that a majority in Convocation are still disposed to regard the University as a manufactory for priests. The Vice-Chancellor, we think it was, said that they did not "want more *apothecaries* and attornies." Under the former designation we suppose the reverend gentleman would include all those students who would devote themselves more particularly

) the natural sciences. But to return: should the Aldri- ıian Professorship not be filled up, we must again insist ıat the funds would be best employed in establishing ıemical scholarships or fellowships which like the adcliffe, should only be held for a limited number of ars.—'Chemical News.'

DR. EDWARDS CRISP ON THE HOMŒOPATHIC TREAT- ENT OF THE CATTLE PLAGUE.—In a letter addressed to e Right Hon. the Lords of the Privy Council, Dr. Crisp ites:—Here, my lords, let me say a few words on the sumed success of the homœopathic treatment in Holland, reported by Viscount Bury at Norwich, although I shall ve occasion to devote one letter to the consideration of s subject. The cures, as reported by Lord Bury, are d to have amounted to seventy-five per cent! My lords, Dr. Hamilton had made himself acquainted with the hology of cattle plague, he must have known that, unless disease assumes a milder type than at present, such an ount of success, under any mode of treatment, is utterly possible. The ten-millionth part of a grain of arsenicum, sphorus, thus, sulphur, or quinine would have, as I ieve, less effect upon this disease than the proceedings of ertain old lady had upon the ocean. The cases treated, ıake bold to say, were not genuine cases of cattle plague. ake the subject of homœopathy the introduction to my ent communication in consequence of the statement le by Professor Simonds at the Farmers' Club, on Mon- last (Nov. 6th), "that Dr. Hamilton would have a fair , and that a certain number of animals would be given im to experiment upon." As Professor Simonds has almost the sole adviser of the Government at this ortant crisis, I presume that this arrangement is made the sanction of your lordships, or by the advice of Royal Commissioners. My lords, it is a very fit and er beginning for the Government, who from the first dealt in infinitesimals, not only as regards the pre- ion of the spread of this disease, but also in relation to ıount of knowledge that might have been obtained, e advice I gave in my first letter had been adopted. eriments, unless they are carried out on a large scale, ıot only useless, but they are sure to lead to injurious .ts. If these trials be made, certain regulations must lopted: experiments practised on eight or ten animals lead to no satisfactory conclusions. A hundred cattle ıst would be necessary; and even then, unless very ite and careful records are kept as to the exact stage disease, the symptoms, the dose of the medicines ıistered, no good will follow. In addition, moreover, ry twenty animals treated homœopathically, twenty be left entirely to nature, so that it may be seen er the "do-nothing treatment" and the globular do nount to the same thing.

ER IN MANCHESTER,—At a special meeting of the on Board of Guardians the consulting Medical officer workhouse read a report showing an alarming increase s of fever lately. He said as many as fourteen persons en admitted into the house in one day, and at one he number in hospital amounted to fifty-two. During t four months considerably more than 100 cases of or typhoid, many of them of the most malignant ıad been under treatment at the Union Hospital. ributed the cause of this lamentable state of things ally to the neglect of the most ordinary laws of and to the pollution of the neighbouring streams vage.

ALEN COLLEGE, OXFORD.—Sir Benjamin Brodie, .A., Baliol College, has been appointed by the above Waynflete Professor of Chemistry. The acceptation appointment will render vacant the Aldrichian Pro- ip of Chemistry, in the Gift of the University, which now be filled up.

APPOINTMENTS FOR THE WEEK.

DAY, NOV. 29.—*Operations* at Middlesex Hospital, 1 St. Mary's Hospital, 1½ p.m.; St. Bartholomew's tal, 1½ p.m.; St. Thomas's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Hunterian Society, 7½ p.m.—Council.—8 p.m. Dr. M'Donnell, "On a Case of Tubal Fœtation, with Remarks."

THURSDAY, NOV. 30.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; King's College Medical Society, 8 p.m.—Mr. Fenn, "On the Pathology of Epilepsy."

FRIDAY, DEC. 1.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.; Archæological Institute of Great Britain and Ireland, 4 p.m; Western Medical and Surgical Society of London, 8 p.m.—Mr. T. Holmes, "On Sub-Periosteal Resection, illustrated by a Case of a Resection of the Entire Shaft of the Tibia."

SATURDAY, DEC. 2.—*Operations* at St. Thomas's Hospital, 9½ a.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

MONDAY, DEC. 4.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metropolitan Free Hospital, 2 p.m.

TUESDAY, DEC. 5.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Cholera Prospects, compiled from Personal Observation in the East. By Tilbury Fox, M.D. London: R. Hardwicke.

Practical Observations on the History, Nature, and Treatment of Cholera Asphyxia. By John Coghlan, M.D. Dublin: Fannin and Co.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the Office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause, and have made such arrangements as will prevent the possibility of a repetition of the omission. Any gentleman not having received his copy as usual during the last six weeks, will be kind enough to intimate the same to the Publisher.*

DR. H. S. PURDON.—The communication is inserted.

MR. R. GOODALL.—The report is inserted.

TOXICON.—Nitro-benzole is prepared by the action of nitric acid on benzole, which is now obtained from coal-tar. The formula of nitro-benzole is $C_{12} H_5 NO_4 + HO$.

X. Y.—We understand that legal proceedings are being instituted against the notorious offender alluded to.

ALPHA.—The skeleton may be seen in the Museum of the College of Surgeons.

A VOICE FROM THE COLLIERIES.—The case is a curious one, and not very creditable to the parties concerned; but we must make further inquiries before giving it publicity.

DR. C.—We have received the newspaper, but have failed to perceive the pertinency of the remarks made in the article to which our attention is directed.

PALL MALL.—We understand that the individual in question did obtain the diploma of the College. Whether he can be compelled to return it remains to be seen.

THE OBSTETRICAL SOCIETY OF LONDON.—The notice has been received.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 7S FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments forwarded for 6 stamps.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

GENERAL MEDICAL COUNCIL.
32 SOHO SQUARE, LONDON, W.
September, 1865.

Registration at the Commencement

OF PROFESSIONAL STUDY.

NOTICE is hereby given, that Regulations for the Registration of Medical Students have been sent to all the recognised Schools of Medicine in England. Students commencing their studies are directed to apply to the Registrar for England, according to the Form with which they will be supplied on application to the several Qualifying Bodies, or at the Schools of Medicine and Hospitals.

Hospital for Diseases of the Skin,

Blackfriars.—To Surgeons.—The Sub-Committe for the appointment of Medical Officers to this Hospital require the addition of one Surgeon and one Assistant-Surgeon to their present Staff.

Candidates for these appointments must be Fellows of the Royal College of Surgeons of England, not practising Pharmacy, and must adduce evidence of having given attention to the study and treatment of Cutaneous diseases.

Applications and Testimonials must be sent under cover to the Secretary on or before December 11th, endorsed, "Medical Officers' Application."

By Order of the Sub-Committee.

ALFRED S. RICHARDS,
Secretary.

Christmas Accounts.—Merritt and

HATCHER will send, post free, on receipt of four stamps, a variety of Samples and Prices of MEDICAL BILL FORMS, by which a great saving of time in making out accounts is effected.

Merritt and Hatcher, Printers, Engravers, and Lithographers, 2 Grocers' Hall Court, Poultry, London, E.C.

Dinneford's Fluid Magnesia,

now Perfect in Purity and Strength.

"Mr. Dinneford's solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

Sold in Jars for the use of Medical Men and Chemists, at 9s. 6d. per Gallon, Half-Gallon 5s. 6d., by the Manufacturers.

DINNEFORD & Co.,

PHARMACEUTICAL CHEMISTS,

172, New Bond Street, London,
and all Wholesale Druggist and Patent Medicine Houses.

Aloina.—T. and H. Smith, the

Discoverers of this,
THE CRYSTALLINE PURGATIVE PRINCIPLE OF ALOES,
(vide 'Edinburgh Monthly Journal of Medical Science' for Feb. 1851,) continue to prepare and supply it. They have the gratification of knowing that the most eminent of the Profession prescribe it, to the exclusion altogether of the various kinds of aloes.

Orders executed direct, or through any Drug House, by T. & H. SMITH and CO., 69 Coleman street, City, London and 21 Duke street, Edinburgh.

Geo. Smith and Co.'s Pure Extract

of CALVES' FEET for INVALIDS and CULINARY USE. Sold in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Druggists, Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland street, Regent street Office: 94 Upper Thames street, E.C.

Pepsine and Pepsine Wine.—Boul-

DAULT begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Chemist in Ordinary to the Queen and H.R.H. the Prince of Wales, 227 Oxford street, London, to whom all applications respecting it must be addressed.

Third Edition, with Further Remarks by Dr. CORVISART, Physician to the Emperor of the French, edited by W. S. SQUIRE, Ph. D.; published by J. Churchill, London; may be also had of the Author, 277 Oxford street, price Sixpence.

The Technologist, Vol. V., edited by

P. L. SIMMONDS, Esq., is now ready, price 14s. Bound.
*** The November Number, just published, price 1s.

CONTENTS:—The Arms Trade of Belgium. By Mr. Barron, Her Majesty's Secretary of Legation at Brussels.—The Oak Silkworm of China. By Thomas Taylor Meadows.—Notes on Coal and Fuel.—Formosa Camphor.—The History of Commerce.—Propagation of Trout in America.—Cleveland Wine.

Kent and Co., Paternoster row, and all booksellers.

Treloar's Kamptulicon,

COCOA-NUT MATTING,

AND OTHER DURABLE FLOOR COVERINGS,
67 LUDGATE HILL, LONDON,
Three doors from the Railway Bridge.

PRIZE MEDAL AWARDED, 1862.

MEASUREMENT: circumference at ABC.

Ladies' Belts.—

The increasing demand for these supp[orts] has caused W. H. BAILEY to DEVOTE PARTICULAR CARE to their MANUFACTURE. They are made of various qualities and prices to suit all who are suffering from the complaints INCIDENTAL TO FEMALES.

Prices, 10s. 6d., 15s., 21s., 31s. 6d., and 42s

PROLAPSUS UTERI.

W. H. B. has effected great improvements in the construction of Appliances for the relief of those suffering from this complaint. They are easily adjusted, and may be sent by post.

ELASTIC STOCKINGS, &c., for VARICOSE VEINS.

A female in attendance.

W. H. BAILEY & SON,
418 OXFORD STREET, LONDON.

T. & H. Smith's Codeia Lozenges.

These Lozenges have a remarkable effect in allaying COUGH, IRRITATION of the THROAT and CHEST.

Prepared only by T. and H. SMITH and Co., 21, Duke Street, Edinburgh; and 69, Coleman Street, London; in Boxes at 1s. 1½d. and 2s. 9d. each.

Medical Fixtures and Glass Manu-

FACTORY, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Assisting in the above Profession, that he has an extensive assortment of SHOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c. of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc

Brass and Zinc Door-Plates

—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges. Chemists' Shops fitted up with Window-sill Plates in the plain or Ornamental Patterns. Lists of Prices post free.

Plates altered and repaired.—Country orders punctually attended to.

36 CHANDOS STREET, CHARING CROSS, W.C.

H. Silverlock's Medical Label Ware-

house, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctor's Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.
YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.
SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.
LABEL CASES for the use of Surgeons, 14s., 18s., and 24s.
LATIN SLIP LABELS for Wholesale Druggists.
Catalogues sent on application.

The Medical Circular.

DR. EDWARDS CRISP ON THE CATTLE PLAGUE.

The preservative power of Nature is so potent that men, and the lower animals also, will get well in spite of the officiousness of the doctor. As reported in the Medical Times and Gazette,' Dr. Colling, Massachusetts, U.S., stated at the Medical Society of that place, that during the epidemic of typhus in 1847-48 he took care of 300 cases of this fever *without administering drugs*. The cases were taken indiscriminately, and included those in a dying state. The result was 31 deaths in 307 cases. In an epidemic of scarlet-fever, 1848-49, out of 81 cases so cared for, 77 recovered. In 1849, of 40 cases of measles treated without drugs, 39 recovered. In the 'Dublin Medical Press,' Oct. 25, 1865, p. 388, in Dr. Nicholls' Medical report of the Langford Poor-law Union, of 135 cases of fever treated without stimulants, 7 died; and of these some were admitted in a hopeless condition. Of 47 cases of small-pox, 1 died. Of 30 cases of scarlatina, 3 died. Of 220 cases of measles, 11 died. Dr. Nicholls remarks that he still continues the unstimulating mode of treatment, that for sixteen years he had found so successful. Dr. Mills, of Dublin, as mentioned, in his work on the utility of bloodletting in fever, 1813, states that he treated 504 cases of typhus by small bleedings from the arm; out of these only 18 died.

I allude to these cases—and they might be multiplied to a great extent—for several reasons. First, to show that if the patients had been treated by globules, the result could scarcely been more successful. Secondly, to endeavour to convince the modern advocates of stimulation in *all* disease that patients *may* recover from fever without alcohol. Thirdly, for the purpose of showing that vitiated and impure blood may be taken from the body in typhus fever without killing the patient; and lastly, to especially exhibit the great difference between the mortality of the cattle plague and human typhus.

With these preliminary remarks, I proceed to the main purport of my letter—viz., as to the resemblance the so-called cattle murrain bears to typhus or typhoid fever in the human subject. On Monday last, at the meeting alluded to, Professor Simonds told the farmers *that the disease was of a typhus or typhoid nature, but that he thought it more like phus fever*. As you are probably unacquainted, my Lords, with the history and practice of medicine, I will endeavour to make my remarks as plain and intelligible as possible, so that they may be understood by all. My previous conclusions have been the result of my own observations, but in the following *resumé* I shall have to borrow largely from the best writers upon the subject of fever, many of whom have added valuable statistical information to their works.

In this country we have four fevers that prevail at certain times, but one (the typhoid) may be said to be endemic, as it is rarely or never absent:—1st, The simple fever; 2nd, The typhus; 3rd, The relapsing or "famine" fever; 4th, Typhoid fever. Some suppose that these fevers are not specifically distinct, but only varieties of the same affection; this, however, is not the general belief, and it was only until about the year 1835 that the differences between these fevers was clearly recognised.

I need say but little about simple fever, as it does not arise like the others from a specific poison. These fevers may be generated spontaneously, or they may arise, as is generally the case, from causes that are under human control. There are some who deny that these fevers are contagious; but their number is gradually diminishing. As my object is to make a brief comparison between the symptoms and morbid appearances of the three last-named fevers and those of cattle-plague, I will give a short outline of the important features of each. In all there are premonitory symptoms which are well known—heat, chills, languor, headache, dry skin, and quick pulse. The exact period of incubation is unknown, but it may probably vary from one to twenty-one days; some believe the period may be much longer. In the relapsing fever the premonitory symptoms are generally less marked.

Typhus, as is well known, has at various times made fearful ravages in camps, jails, and crowded and unhealthy localities; but in no instance on record has it spread in the same manner as cattle-plague; indeed, as I said before, there are some who question its contagious nature—isolated cases both of typhus and typhoid fever often occurring without their being communicated to the attendants; in this respect forming a remarkable contrast to the contagion of cattle-plague. There is another most important symptom absent in typhus and in relapsing fever—viz., diarrhœa; for, as a general rule, the bowels are constipated in these affections. In typhus a rash appears upon the skin from the third to eighth day; but is not renewed as in typhoid fever.

In the relapsing or famine fever there is no eruption. This fever, as is well known, is the attendant on partial starvation, and on the deprivation of the ordinary necessaries of life; whereas the typhoid fever, unlike the two former, attacks people that are well fed and in good circumstances. In this fever a relapse generally takes place on the fourteenth day, and this may be repeated two or three times.

The typhoid fever, constantly present in this country, is, like typhus, attended with a skin eruption, appearing between the seventh and fourteenth days, sometimes very slight and scarcely perceptible; but, unlike the eruption of typhus, it appears and disappears, its duration varying from fourteen to twenty-one days. This fever is not, like the others, so dependent upon unhealthy localities, bad ventilation, and aggregation of persons. It more frequently attacks young persons; and after a certain period, is attended with tenderness about the abdomen, diarrhœa of an offensive character, the evacuations being of a dirty-yellow colour, and showing a great tendency to fermentation. The appetite is less impaired than in typhus, and the fever is not so contagious.

The duration of these fevers varies from three to six weeks, and the mortality in hospital and workhouse practice from 2 to 18 per cent., the famine fever being much less fatal. I believe in private practice the fatality is less. I have only given a brief outline of the characters of these fevers; but it is enough for my present purpose, Delirium, twitching of muscles, brown and dry tongue. petechial spots, and other symptoms may be present, according to the nature of the fever and the stage of the disease. By some, typhus and typhoid fever are classed with the exanthemata; but, in speaking of exanthematous affections, I adopt the ordinary acceptation of the term, including scarlatina, measles, small-pox, &c.

We now come to the morbid appearances in these fevers, which are very important *by way of comparison*. For typhus fever there is no specific lesion; the organs generally, from the impure state of the blood are preternaturally vascular, the lungs congested, and the spleen and other parts softened; *ecchymoses* may occur in the intestinal mucous membrane, and other accidental complications may exist, as in the other fevers.

In the relapsing fever the spleen and liver are generally enlarged, especially the former, and these are the chief morbid alterations.

In the typhoid fever, Peyer's glands and the solitary glands in the lower part of the ileum are generally enlarged and ulcerated, forming, in this respect, a remarkable contrast to the state of the intestinal mucous membrane in cattle and sheep-plague. The mesenteric glands, too, in this fever are enlarged, and contain a peculiar deposit; whereas in cattle-plague they are nearly in a normal state.

So, my Lords, if we look to the chain of symptoms—to the morbid appearances—to the duration, the rate of mortality, and to the comparative contagious nature of the fevers of this country, and to the like matters in cattle and

sheep plague, we finn such manifest and essential differences that the terms "typhus" and "typhoid," as employed by the government and its advisers, must be abandoned. It is this error on the part of your Lordships' advisers, I believe, that has led to such disastrous results as regards treatment; for persons believing, on what they consider to be *high authority*, that this disease is typhus fever, have poured stimulants and irritants into the stomachs of oxen, cows, and calves without limit, and in this way, as I believe, have greatly increased the mortality; globules and infinitesimals, although I deny their efficacy, would have had this merit at least, that they *could have done no harm*, and nature might in some cases have righted herself.

"CYCLOPS'" THIRTIETH LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—To continue the subject of the fat in the body from my last. It is fully admitted that the oxydising processes in the system are very great and continuous; then if this is the case, there must always be opposing elements in the same proportion; oxygen and carbon would soon wear and burn the body up, if it were not for the hydrogen. Now as we live in a gaseous element, the very fact of this wonderful organism of gases, which is perpetually changing and producing the phenomena we see, of wind, rain, storms, snow, lightning and thunder, and even solid bodies such as aërolites; yet it is always returning to a state, sufficiently fixed for animal and vegetable life. Besides this, it exercises a pressure on the body of fifteen pounds to every square inch; so that it would seem that much oxygen must always be actually forced into it. The resistance to this must be what the body makes within itself. Now, as chemists can reduce all matter to certain component elementary parts uniting in certain atomic proportions according to Dalton's theory, I cannot but wonder at the silence on the subject of the actions of the gases in the body, I have therefore suggested the idea of many fluids having their origin in the body, independent of the blood, to the refutation of the belief that they are produced from the blood, which appears to me to be unintelligible and inconsistent, as well as untenable and impossible. Our latest writers on the nature and formation of fat, say, "All fatty acids combine with a base to form a soluble compound." Well, this we will imagine as near an aqueous one as it is possible to be, because they go on to say,—"this is carried into the blood, where it is again formed into an insoluble compound when it is deposited as fat." Now, "how in the name of all the gods at once" can an insoluable compound permeate such membranous structures as the arterial by exosmose and this substance too, to be fat. It is quite a gratuitious theory, and quite incomprehensible and only made to uphold the fixed idea, that every element must first go into the blood for every other element to be made from or out of it. It seems to me a very roundabout way for Nature to do very simple things when she can do them so much better and easier and does so, whatever physiologists believe or say to the contrary, as I have already set forth. Now, I apprehend that the real positive fatty elements of food are used more by her to make hydrogens in the system and suspend and retain them, or she would not have been so careful in her provision of forming bile to saponify them. These saponaceous or fatty particles hold immense quantities of hydrogen, so that uniting with oxygen in the alimentary canal, even in the state of new ingesta, may actually double or treble the quantity and bulk of chyle; thus enabling the small intestines in their knuckling and millstoning process to press into the lacteals, all the necessary elements to be derived from the whole mass; while on the other hand all the insoluble portions are carried into the colon where oxygen does not permeate. The very fact of the solid masses sent there, becoming fæces, immediately make a large quantity of hydrogen, which by exosmose passes through the membranous coat and then meeting with oxygen and carbon, aqueous elements are formed and become condensed wherever they can be deposited, in the shape of adeps or fat. There can be little doubt, as physiologists say, that fat is a fuel of the body, and the more oxygen there is consumed, especially in summer, the fatter the body becomes, and that the concentrated cold air of winter consumes it more rapidly and the body gets thinner. Now here again physiologists spoil everything and refute themselves; for they say,—"These facts show that the influence of the fat is to *supply the blood, when destitute of combustible materials with a quantity of fuel for combustion.*" Can anything be irreconciliable with common sense. Really this fat is made to do such strange things that if nobody ever heard of it before, instead of its being an ingenious theory worked into the minds of men by degrees and there finding some repose, they would be perfectly astounded at it. What a combustible material the blood must be! But I deny all these doctrines *in toto*. Let me only refer to the character and constituents of the blood corpuscles, from whence it may be supposed the fatty deposits are produced. Their chemical composition in 1,000 parts are, water 688 and solids 312. Of these solids, globulin claims ninety and Hæmatin five per cent; the remaining five per cent. consists of fat, extractive and mineral matters, and salts. The fat is small in quantity but yet larger than in the liquor sanguinis. The principal acid of these corpuscles is phosphoric and the principal base is potash, which no doubt keeps the fat saponaceous: so that if we divide the fat, extractive and mineral matters and salts in equal parts, we find one and quarter of each for every 1,000 parts scarcely an eighth per cent. to be the prime depositor of one twentieth part of the weight of the body. Taking all the circumstances together I think this a very convincing proof that the fat cannot be formed from any deposition or exudation of the blood. It appears to me that what there is in the blood is only a sufficient proportion for the necessary lubrication of the vessels themselves through which it passes, and only justifying physiologists in saying that it is one of its elementary constituents and no more.

The fact explains itself that the body makes more fat in the summer and consequently has greater powers to store it by inspissation, in the form of fat than in the winter as the greatest real combustion that is always taking place in the body is by the assistance of the gases; their rapid transit and consequent various formations from them; the resistance they offer to atmospheric pressure by actually adhering it and using it and all this too outside the blood vessels and not in them, and having little or no connection with the arterial currents. There is no doubt that oxydising influences take place within them, as well as everywhere else, but the two actions are distinct. This is shown particularly at their termination, namely in the capillaries, which will not pass blood without oxygen, and oxygen is the natural stimulant of veins. In all this imaginary circumlocution of fattydeposits and how Nature acts, physiologists conclude by saying that, "At any rate, however far we may be from comprehending the exact nature and seat of these changes, there can be no doubt that starchy and saccharine food is capable of being converted into fat." In this I am sure nobody can differ in opinion, but if we can only get meat or fat by consuming fatty and oily things or those which produce fat, we have a right to ask where the vegetable kingdom, which produces such quantities, gets its fatty oily matters, whether it be a cereal, or a tree, or their nuts such as linseed, colza, &c. How are these obtained? Not as is inferred by the physiologists as to the body, by being manured with oil and fat; but by that peculiar combination of the hydrogens, carbons and oxygen, which we see in the natural combination in these plants to produce fat, and which are the very self-same processes that are performed in our own bodies, independent of our food, which must be admitted assists largely, but does not wholly cause the secretion. Some persons are careful not to take the slightest portion of fat in their food, yet they cannot eat anything without getting its elements. Fat must therefore, in the healthy body be always in a mechanical condition, easily acted upon both by heat and cold. It is in every part the nucleus of moisture and the pure and lakes and standing waters. As an inspissated

ll times ready for reduction to a fluid state. It is the reat sponge or filterer of fluids to absorb gases and to thale them. Being rich in hydrogen it absorbs the oxygen id becomes a fluid. The electric heat given out in all their nions produce carbon or warmth. Along the nerves it nstantly supplies that moisture which is wanted for their ectrical actions as much as the fluids in galvanic troughs. ow deficient are patients under fevers of nervous powers sympathies; and in delirium from want of these fluids, nsation ceases and the nerves are powerless to feel or preciate. The soft unctuous state of all our tissues, ous and mucous membranes, fasciæ and interstices, all ow the value of the aqueous matter from fatty deposits. t to say that all this is a deposit from the blood, when system has the same laws and power of using them and nsequent means to make this adeps independently of the od equally as the plants and cereals, is a mere assump- n the sooner it is banished from physiology the sooner l some truth dawn on natural laws. The actions of the es of the body, for which I am contending, are ill under- od. Even the blood is imperfectly known, for it has dently given to it, too much to do. Rich as the arterial culation is, with all matters to preserve and renovate ncture it is to me an impossibility that it can deposit fat l make secretions as well. We give acts to vegetation n certain elementary laws and deny the same to the ly, which has precisely similar ones for the same purposes. admit one can do a thing, but that it is done by a erent law in a higher organism, while the same laws duce precisely similar results. The heart cannot act hout its due supply of lubricating fat or grease, hence it lways well supplied with fat on its upper portion; nor any other muscle. The highly sensitive state of the ly could not exist without an immense supply of fluid ependent of the natural blood currents. Unless a large ount of fluid was made in the body independent of what drink, neither digestion, chylification nor appropriation ld go on. The changes which take place, of conversion n albumen into gelatine in the mesenteric glands could take place without independent fluids. Nor could the vary glands eliminate their secretions without them; l lastly, the secretions of the kidney from the blood ld not pass without the assistance of these independent ds.

The amount of fat in the body and the general plumpness mbonpoint of individuals are always in ratio to the size calibre of their colons. The fæces being the prime lucers of the hydrogens, it is seen that thin persons do make so much fat, simply because their fæces have not uch room to act, nor are their colons expansive enough he generating of this gas. They have upon a broad ciple a more conserved and constipated idiocyncrasy, they make enough fat, and consequently enough ous matter for all the purposes required. Neither do as a rule perspire so much as the fatter individuals; re nevertheless equally healthy, wiry and long-lived. gradations in size of individuals depend upon the colon, hose with prominent Falstaff abdomens show them ve large colons, especially transverse arches of that s. They are more dependent for this bulk on the e and size of the colon, than on the stomach, duo- n or small intestines. Even if they have, as they do, more actions on the bowels than the thin wiry ct, their fæces exhale more hydrogen and they absorb n more readily and in far greater proportions. It m happens that individuals of this character have less two actions on their bowels every day and often more, hey secrete saliva, perspire and micturate in propor-

They lay up great store also of fat everywhere, such the omentum and about the kidneys and glands. I long come then to this conclusion, that the fatty and matters we consume are necessary to attract and absorb ygen from the immense amount of hydrogen they n, and that these form additional aqueous fluids in rocesses of digestion, while the refuse from these ses goes into the colon to help these fæces in the tion of hydrogen, which by excosmose permeates it ghout all its wonderful length and as the colon does not receive oxygen the quantity generated is something enormous, and were it not for this, as well as the other gases, such as sulphur, phosphorus, &c., we should not have the animal and vital life and existence which we now exhibit. It is for purposes of the kind above stated that the Esquimaux and other inhabitants of the Polar regions require so much blubber. On the other hand, instead of the fat which we take in our diet, making fat in the blood and the blood depositing it; which I hold to be a false theory from beginning to end; the fat is an extraneous deposit from other sources such as I have herein set forth. Other uses of this wonderful and beautiful structure I shall reserve for my next.

I am &c., Cyclops.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

REVIEW OF THE PERIODICALS.

The 'Lancet.'

Dr. Barnes continues his lectures "On Puerperal Fever," and he now treats of the means by which this disease is propagated. The principal sources of the fever are an animal poison generated by the crowding of lying-in women together; bad sanitary conditions; exposure to some contagious disease; and direct inoculation of cadaveric matter, or of other animal poison, by means of persons coming into contact with the lying-in woman. Dr. Barnes especially considers the question of poisoning by cadaveric matter, and he concludes that although this matter is one of the causes of puerperal fever, it is not the sole, or even a common cause, but that the matter from bodies which have died of infectious or zymotic disease is a very dangerous element in producing the malady. He then considers the relative influence exerted by Medical men and nurses in the propagation of the fever, and he concludes that the latter have the greatest share in the result, because they are more in contact with the patients and remain longer with them, and often neglect a change of clothes. He recommends that nurses should be relieved of their duties two hours each day, that they should wear white cotton dresses, that they should take a warm-bath once a week, and that if they have been in attendance on a case of puerperal fever, they should not attend another case of midwifery for at least a fortnight.——Sir Ranald Martin communicates "Some Observations on Hepatic Disease amongst Europeans in the East Indies," his present subject being "Chronic Enlargement of the Liver." In this affection mercury is injurious rather than beneficial, although this metal was formerly employed as an alterative in chronic as well as acute affections of the liver. But Sir R. Martin believes that mercury, improperly used, actually causes hepatic enlargement.——Dr. W. H. Stone, of the Brompton Hospital, contributes a paper "On Madeira," in which he briefly describes the nature of its climate in reference to the treatment of tubercular consumption. Although he believes that the effects of the climate of Madeira in this disease have been unduly extolled, he thinks that a certain class of pulmonary invalids may derive benefit from residing there, especially those in whom the progress of the disease has been arrested. The writer mentions parenthetically that the cultivation of the vine, suspended for many years in Madeira, has been resumed during the last two years, and that the production of wine is now very considerable.——Dr. John Brunton describes and figures a "New Otoscope or Speculum Auris," the ad-

vantages of which he believes to consist in simplicity of construction, ease of application, precision and minuteness with which the ear may be examined, and some other points.——Dr. R. P. COTTON offers some "Notes on a Certain Form of Hæmoptysis, unassociated with Pulmonary Tuberculosis." After remarking that hæmoptysis is usually regarded only as another name for phthisis, he states that he has frequently seen cases of spitting of blood in which there was no tubercular deposition in the lungs, and he then describes three cases in which there was hæmoptysis but no phthisis. His conclusions on the subject are as follows:—

"1st. There is a form of true hæmoptysis in which the expectoration is of a dark colour, and of a more or less watery consistence, bearing a close resemblance to a mixture of red-currant jelly and water.

"2nd. That such hæmoptysis is of non-tubercular origin, and may proceed from any part of the gastro-pulmonary mucous membrane.

"3rd. That it is attributable to a morbid and fluid condition of the blood, allied, at least in appearance, to that which is met with in purpura and scurvy."

——Dr. L. W. SEDGWICK, in a "Note on Uric Acid," adduces a case to show an exception to the rule given in the text-books that pale deposits in the urine dissolved by heat are urates, and that deposits of uric acid are not dissolved by boiling. In the case described, the uric-acid crystals were dissolved by heat.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. BENCE JONES continues his lectures "On Local Chemical Disorders arising from Suboxidation, and their Mechanical Results," his present subjects being the "Effects of Intense Cold," and "General and Local Fatty Deposit and Production." He shows that the process of fattening, whether natural or artificial, is caused either by taking more fatty matters into the system than can be removed by the influence of oxygen, or by diminishing the quantity of oxygen supplied to the tissues. Dr. Jones relates a series of experiments made upon the lower animals by the administration of phosphorus, the result of which is to produce acute fatty disease in consequence of the phosphorus suddenly diminishing the oxygen in the body. Phosphoric acid produces the same effect.——Dr. GEORGE HARLEY continues his course of lectures "On the Urine and Diseases of the Urinary Organs," his present subject being "Albuminuria." The morbid conditions which are characterised by the presence of albumen in the urine, although sometimes all classed together under the name of Bright's Disease, really arise from very different causes and necessitate a new arrangement. Dr. Harley therefore proposes a classification of such cases under several distinct heads, according as the disease is temporary or permanent, traumatic or idiopathic, and according to the complications it may present. In some cases the disease originates in the kidney; in others the kidney is only secondarily affected. The rest of the lecture is devoted to the consideration of acute albuminuria or nephritis, to which Dr. Harley proposes to restrict the term "Bright's Disease," as this is accompanied by dropsy.——Dr. JOHN W. OGLE communicates some "Reminiscences of the Cholera at St. George's Hospital in the years 1849 and 1854." There were eighty-six fatal cases of cholera treated in the hospital, fourteen in 1849, one in 1853, and seventy-one in 1854, and the symptoms, treatment, and post-mortem appearances are given in thirty-six cases. Among other remarks made by Dr. Ogle, it appears that in some of the cases there was preliminary diarrhœa, and in others this symptom was absent.

REVIEW OF BOOKS.

The Optical Defects of the Eye and their Consequences Asthenopia and Strabismus. By John Zachariah Laurence, F.R.C.S., M.B., Surgeon to the Ophthalmic Hospital, Southwark, &c. Pp. 112. London: Robert Hardwicke. 1865.

Mr. Laurence's work is a valuable contribution to English ophthalmic literature. Whilst it may be said to be a faithful exponent of the views held by the modern school of ophthalmology respecting the anomalies of refraction and accommodation, it presents evidence of a large amount of original observation. Mr. Laurence, as he informs us in his preface, has had the advantage of studying the optical defects of the eye at Professor Donders' clinic in Utrecht, in addition to which he has spent several years in the observation and treatment of cases at the Ophthalmic Hospital, Southwark. The work before us is the result of that practical experience, and in order to give a general idea of it, we shall proceed to a brief analysis of each chapter.

Mr. Laurence prefaces the main subject of his book by a chapter of "optical considerations." It is to the absence of any such preliminary information that he ascribes the unintelligible character which most of the communications hitherto published on this subject have possessed for the Profession at large. In Chapter I. the nature of light and the actions of lenses are discussed, and plentifully illustrated by wood engravings. Chapter II. treats of "Physiological Optics." After describing the alterations which take place in the course of parallel rays of light in their passage through the refractive media of the eye, Mr. Laurence proceeds to a consideration of the power of adjustment. He considers with Young, Max Langenbeck, and Cramer, that the phenomena of adjustment are produced by a change in the convexity of the crystalline lens and he explains in a clear and concise manner that the increased convexity of the lens for the focussing of divergent rays of light upon the retina may be illustrated by supposing it to be equivalent to an actual superimposition of a convex lens on the anterior surface of the crystalline when at rest; the focal length of the imaginary auxiliary lens being exactly sufficient to convert the divergent, into parallel rays before they are convexed to their focus upon the retina. Mr. Laurence next discusses the various opinions in reference to the "mechanism of accommodation," from which we gather that he inclines to the views of Porterfield, H. Müller, and Helmholtz, that the ciliary muscle is the active agent in the act of accommodation, and that the iris is not an essential part of the accommodatory apparatus, although there is no doubt that it assists materially by its movements to increase the definition of the retinal images. This chapter concludes with a description of "Binocular Vision."

The first twenty-nine pages, devoted by the author to these preliminary observations, embody in a short space all the essential optical information for the proper consideration of the optical diseases of the eye. This information is, as far as we are aware, not given in any similar modern work in the English language. The following three chapters are respectively devoted to myopia, hypermetropia and astigmatism, each of these anomalies of refraction being illustrated by cases.

At page 38, Mr. Laurence relates an interesting case of progressive myopia of 1-1⅞, unaccompanied by staphyloma posticum or buphthalmos. At page 40, a rather novel, but exceedingly useful optometer is described, which consists of an ordinary shoemaker's rule, the fixed upright serving when notched out for the reception of the patient's eye and the sliding upright for the attachment of the test-type.

At page 44 reference is made to the very distressing "dazzling" experienced by high myopics in the employ-

ment of their reducing glasses, "causing such patients invariably to prefer lower glasses to those which completely neutralise their myopia." Mr. Laurence informs us that he has succeeded in finding the remedy: "it consists simply in tinting the glass." Two cases are next given which evidence the utility of this plan of treatment. Chapter V. contains a clear and concise exposition of the phenomena of astigmatism, and the rationale of the action of cylindrical lenses.

The anomalies of accommodation—viz., Presbyopia, and Paralysis of Accommodation, are treated of in Chapters VII. and VIII., the latter disease being illustrated by elaborate reports of several cases in which the Calabar bean was employed and the effects carefully noted. The concluding chapter is upon "the connection between convergent strabismus and hypermetropia.

Mr. Laurence furnishes statistics of the acuity of vision in thirty-three cases of unilateral convergent squint, the object being, to show that the duration of a squint powerfully influences the diminution of a patient's vision, pointing clearly to the necessity of performing tenotomy at a much earlier age than is usual for its practice, in order to avoid the total and irretrievable exclusion of the squinting eye from the act of vision.

Patients suffering from optical defects of the eye form a very large proportion of the cases which present themselves to the ophthalmic surgeon. It is strange, therefore, that until recently these diseases should have been surrounded by so much mystery and confusion. Now, however, the veil is removed, and these affections are reduced to a scientific and satisfactory system. To all those who wish to acquire a sound knowledge of these diseases, we advise a perusal of Mr. Laurence's work. To the general practitioner it presents a faithful epitome of the existing state of our knowledge of the optical defects of the eye, and to the ophthalmic surgeon it affords information and statistics well worthy of his consideration. We may finally mention that the book is illustrated throughout with figures so clear, as to materially assist a practitioner in thoroughly understanding the work before him.

On Flooding after Delivery, and its Scientific Treatment; with a Special Chapter on the Preventive Treatment. By Lumley Earle, M.D., Obstetric Surgeon to the Queen's Hospital, Birmingham, Honorary Medical Officer to the Hospital for Sick Children, &c. Pp 244. London: Hardwicke. 1865.

Of all the dangers which accompany the process of parturition, hæmorrhage is avowedly one of the most formidable, and most rapidly destructive to life. In no circumstances connected with attendance on lying-in women are promptness of action and coolness of judgment more necessary on the part of the practitioner than in this serious complication, and on no point of obstetrical surgery ought the student to be better informed. In nearly all other complications and accidents of the lying-in condition, it is possible for the Medical attendant to seek for advice and assistance under the pressure of dangerous symptoms, but in the instance of post-partum hæmorrhage he must be prepared to act energetically and at once; and on the course he adopts will the life of his patient in many instances depend. Dr. Lumley Earle has therefore done a good service to practical midwifery in choosing this subject for his present book, and in pointing out clearly the dangers to be apprehended, the methods of distinctly recognising their presence, the means to be adopted to obviate their results, and the precautions to be taken to prevent their return.

Dr. Earle is well qualified by his previous training and his present professional position to write on such a topic; for after filling with credit the post of physician-accoucheur's assistant at King's College, London, he performed for some time the laborious duties belonging to the office of Resident Surgeon-Accoucheur to the Birmingham General Dispensary, and he now holds an important obstetric appointment in the Queen's Hospital in the same town. He has thus had ample experience of the phenomena attending the parturient state, and his views and opinions are therefore founded upon, and strengthened by personal observation.

After describing the signs and symptoms of post-partum hæmorrhage, Dr. Earle devotes a chapter to "Preventive Treatment," on the importance of which he insists the more strongly, because he believes that at least half the number of cases in which this accident occurs might be prevented by ordinary care on the part of the Medical man or the patient. The precautions which may be employed to prevent flooding after delivery should have for their aim the two points of perfect rest of body and perfect contraction of the uterus, and minute directions are given in order to effect these objects. Among other precautions the use of a binder adjusted *before* the termination of labour is strongly enjoined, as any exertion on the part of the mother after the delivery is thus avoided, and the binder can be more easily and more equally applied. Another important precaution is to take care that the placenta is expelled soon after the birth of the child, and if this is not done by the natural efforts, then manual assistance should be cautiously rendered. No definite time, however, is prescribed for the removal of the placenta, but it is recommended that it should be withdrawn as soon as it is known to be detached, and the placenta and membranes should be thoroughly examined to ascertain whether they have come away perfect. In reference to the proposal of Dr. Rigby to apply the child to the breast soon after delivery as a means of preventing post-partum hæmorrhage, Dr. Earle objects that such a plan sometimes causes the mother to make undue exertion, and he therefore proposes a measure which effects the same object but without the attendant inconvenience—namely, to compress the breast with the hand—a proceeding which causes the uterus to contract almost instantaneously, and insures perfect rest to the mother, while it can be kept up for any length of time, and involves no chance of failure in its application.

The remedies for post-partum hæmorrhage consisting chiefly of pressure on the uterus, the application of cold, the administration of stimulants and of ergot, and the introduction of the hand into the uterus, are all briefly but clearly described, and brandy is recommended as a most useful and, indeed, indispensable article to be used in the emergency. "Many a woman," says Dr. Earle, "has lost her life from the want of this agent," and he recommends that it should be given freely, either pure, or diluted with half the quantity of cold-water.

The different conditions causing post-partum hæmorrhage are successively passed in review, both those which exist before the expulsion of the placenta, and those which arise after it, and the accidents of ruptured placenta and retained membranes are fully described; then the author points out that distention of the bladder is by no means so infrequent a cause of flooding as is generally supposed, and he directs particular attention to be paid to this point with a view of removing the obstruction by the catheter.

The more rare causes of post-partum hæmorrhage are then considered, such as rupture of the os uteri, or of a thrombus in the cervix, sloughing of the vagina, rupture of the perinæum, thrombus of the vulva, purpura, polypus, &c., and the concluding chapter is devoted to the after-treatment, including a description of the process of transfusion, and of the instruments by which that operation may be most conveniently performed.

From the above brief notice it will be seen that Dr. Earle has brought together in his very interesting volume many subjects of the greatest importance in the practice of midwifery, and considering the gravity of the affection described, and the plain and concise rules given for its diagnosis and treatment, we feel sure that his remarks will be extensively perused, while his precepts may perhaps be the means of saving many a life, which might, under inefficient or erroneous treatment, run the risk of being sacrificed.

Photographs (coloured from Life) of the Diseases of the Skin. Number X. By Alex. Balmanno Squire, M.B. Lond. London: Churchill and Sons.

The present number of this series presents us with a

photograph of *Erythema tuberculatum*, erythema being selected to represent the exanthematous group of skin diseases. The patient from whom the photograph is taken was a strumous boy, and the eruption appeared on the back of the legs, with somewhat of a symmetrical arrangement. The representation, like the rest of the series, is very good, and the different colour of the patches exhibits very clearly the stages of the disease, the more recent ones being of a rose-red tint, while the older are of a purple or brownish colour.

MEDICAL AND SURGICAL EXAMINATIONS AT THE UNIVERSITY OE CAMBRIDGE.

The Examinations, first and second, for the M.B. Degree, and that for the Degree of Master in Surgery, at the University of Cambridge, have just terminated. The questions proposed are of a very searching character, and the examinations were partly by printed papers, and partly conducted *vivâ voce* by means of specimens and descriptions of cases in Addenbrooke's Hospital. From the extensive series of Examination papers in Anatomy, Chemistry, Physiology, Comparative Anatomy, Botany, Medical Jurisprudence, Pathology, Surgery, Medicine, and Midwifery, we publish the following, which are the respective papers in Medicine and Surgery.

EXAMINATION FOR THE DEGREE OF MASTER IN SURGERY. MICHAELMAS TERM, 1865.

Pathology and the Principles and Practice of Surgery.

1. In what bones is osseous union after fracture the exception rather than the rule? and what is the cause of this in each instance? What are the common causes of failure of osseous union in other bones? In which of these bones does the failure most frequently occur, and why?

2. What are the symptoms of popliteal aneurism? With what diseases may it be confounded in practice? Give the diagnostic marks in each case.

3. How would you distinguish a hydrocele in which the contained fluid is blood-stained, from an irreducible hernia extending to the lower part of the scrotum?

4. Describe the operations in use for the formation of an artificial pupil, indicating the condition of the eye in which each method might be recommended.

5. Give the symptoms and treatment of common inflammation of the hip-joint. What structure is usually first affected? What symptoms would lead you to suppose that the cartilages are affected?

6. What are the usual symptoms of intus-susception of the intestine?

What treatment is, in your opinion, applicable at each period of the disease? State your reasons for the treatment which you recommend.

7. Describe the process of the formation of an abscess and of the advance of the matter to the surface. What is the use of a poultice? Why does the pus usually become collected into a cavity, and under what circumstances is it likely to be diffused?

8. Describe the symptoms of cancer of the bladder and the signs on which you would rely in its diagnosis from the several affections with which it might be confounded.

9. Relate a case of cancer of the tongue. What are the usual microscopical appearances in this disease?

10. In a bullet-wound of the chest, what symptoms would lead you to the conclusion that the lung had been wounded? Point out the degree of importance to be attached to each symptom.

Viva voce Examination.—Examination of selected specimens and examination of patients in Addenbrooke's Hospital.

SECOND EXAMINATION FOR THE M.B. DEGREE. MICHAELMAS TERM, 1865.

Pathology and the Practice of Physic.

1. Describe the symptoms and course of phenomena characterising a complete paroxysm of ague. In what other diseases do paroxysms, more or less resembling those of ague in their periodicity and symptoms, not unfrequently occur?

2. What are the chief peculiarities which distinguish erysipelas in relation to the conditions of its occurrence and to the prevailing type and class of the constitutional symptoms mostly accompanying it? and what does the consideration of these peculiarities suggest as to the method of treatment to be followed in its early as well as in its more advanced stage?

3. In what, besides the uniformity and limited extent of its seat, does the special pathology of lead palsy consist, distinguishing it from most other forms of paralysis? What remedies would you employ with a view to remove this local affection as well as counteract the general effects of the poisoning?

Detail briefly or refer to any case in which the remedies you recommend have been effectual.

4. What do you understand by the term *General Paralysis of the Insane?* Describe the usual course of development of this disease, and especially note the earliest indications of its approach.

5. In auscultation of the lungs describe what is meant by *fine crepitation*. What value do you assign to it as an indication of pulmonary disease? What accompanying signs or symptoms are required to give precision to its import? Taken singly, what are the pulmonary lesions in which it occurs?

6. In what emergencies would you have recourse to puncturing the chest? Would you resort to it only as an extreme measure, or do you think its success is oftener secured by its employment at a comparatively early period. Give reasons in support of your opinion in this matter.

7. What are the varieties of the casts of the uriniferous tubes or other morphological elements discoverable by the microscope in the urine of patients suffering from kidney disease? Can the precise form of the renal lesion be approximately determined, or the prognosis be rendered more accurate by discrimination of these products? If they can, what special form of lesion would you say corresponded to one or other of these casts? Or in the progress of any single case is there any relation to be noticed between the change in the *character* of the casts and the probable change in one direction or another, of the renal lesion itself? If so, specify such relation.

8. Give the diagnostic characters of *Lepra Vulgaris*. Does *Psoriasis* exist as an essentially distinct form of cutaneous disease? If so, what other diseases does it mostly resemble in their chronic stage or inveterate form? Refer to authorities, or state the grounds of your own opinion in this matter.

9. What are the symptoms of the disease called "Laryngismus Stridulus?" What is its probable pathology, and what the treatment that it requires?

10. What are the symptoms of the chronic ulcer of the stomach which tends to perforation, and what should be the treatment?

11. What part of the nervous centres is considered by Van der Kolk as especially implicated in epilepsy? What is the condition of the blood-vessels of that part stated by him to be, as the effect of frequent epileptic seizures? What local treatment does he advocate based on his view of the anatomical relations of the disease?

GENERAL CORRESPONDENCE.

THE COLLAPSE OF THE ICE-BAGS.

To the Editor of the Medical Circular.

SIR,—Your editorial remarks on the ice-bag are both just and fitting, but you are perhaps a little too lenient towards your contemporaries. The value of cold to the back by affusion, ice-filled ox bladders and the like, in those disorders of the nervous system for which the ice-bags were recommended, has been long known to therapeutics, and the use of the cold wet sheet in cholera has

had and still has its advocates. From this point of view the caoutchouc ice-bags could only be looked upon as a method of withdrawing heat from the surface of the body (or of applying cold), the convenience or inconvenience of which experience would determine. The astounding novelty of the thing consisted solely in the hypothesis of the promulgator. Ignoring all experimental researches into the effects of a lower temperature of the skin upon the nerve centres, though the appropriate incident excitor or sensory nerves, or more correctly, perhaps, being entirely ignorant of such researches, he laid it down as a *fact* that where his ice-bags were applied to the back, the temperature of the sympathetic ganglia in front of the vertebral column was lowered by the direct withdrawal of the heat of the body! How the intense ignorance and rashness which this hypothesis revealed escaped the notice of intelligent editors is the marvel; even the two able editors of the 'Medico-Psychological Journal' got into that ice-bag mess. Let us hope our watchdogs will take warning by their sad experience in that affair, and be better dogs for the future.

I am, &c., A READER.

P.S.—Our friend, the 'Medical Times and Gazette,' published some articles on the murders by Forward, whose case the writer strongly prejudged, and in which he falls foul of the "mad doctors,"—such men as Esquirol, Conolly, Pritchard, Laycock—very much in the ice-bag style of ignorance and rashness. I would suggest a revision of opinions in that direction also.

OBSCENE PUBLICATIONS.

To the Editor of the Medical Circular.

SIR,—I think that the Medical Profession, as well as the public at large, are much indebted to "Detector" for his fearless and startling exposure of the system of extortion practised by the obscene Quack fraternity of London, in the letters which appeared in your Journal a few months ago, and are now published in a separate form, and I am sure, I for one, read his astounding disclosures with the utmost amazement, as doubtless did many others.

On Sunday last (of all days in the week), I found my breakfast table polluted by the presence of one of these vile and obscene publications, in the shape of a small cloth bound volume, by Messrs. Harvey, I think, of somewhere in London, upon their so-called "Sir Astley Cooper's Vital Restorative," the second I have received within eighteen months, and which I committed bodily to the flames, there and then.

Now, Sir, I wish to ask you two questions, which form my object in writing this:—

1st. What possible motive can these people have in sending their beastly publications to the Medical Profession, the class of all others most calculated to detect their utter worthlessness and falsity, except it be to offer them a deliberate insult?

2nd. Could not the same law which deals with the distributors of offensive and obscene publications of other classes, be brought to bear upon the gratuitous circulation of these highly injurious and disgusting productions?

A corner in your Journal and an answer to my two queries will much oblige.

Yours, &c., M.D.

Deddington, Oxon, November 28, 1865.

[It is to be regretted that no means at present exist to punish such offenders.—EDITOR MED. CIRCULAR.]

POOR-LAW MEDICAL REFORM.

To the Editor of the Medical Circular.

SIR,—I shall feel obliged for space to lay before the Poor-law Medical officers a list of the subscriptions I have received since the last Report was published, in July. I need scarcely say that, with a debt of nearly 9*l.* still existing, I am powerless for any active exertion, which I much regret, as the annexed letter, received within the last few days, clearly proves that there is great need of an improvement in the position of the Poor-law Medical officers.

Subscriptions received since July 3, 1865:—West Somerset British Medical Association, 2*l.*; Dowling, J. H., Cerne, 5s.; Loveless, W. R., Stockbridge, 5s.; Jardine, J. L. Dorking, 5s.; Prowse, W., Amersham, 5s; Faithorne, G., Amersham, 5s.; Sniethman, G. T., Amersham, 5s.; Brickwell, B. A., Amersham, 5s.; Clarke and Elliott, Barnstaple, 10s.; Rees, H., Amersham, 5s.; Willis, R., Taverstock, 5s.; Jeston, W. and Jeston, R. P., Henley, 20s.; Jackson, T., Gateshead, 10s.

I am, &c.,

RICHARD GRIFFIN.

12, Royal terrace, Weymouth, Nov. 27, 1865

"MY DEAR SIR,—I forward P.O.O. towards expenses of your praiseworthy endeavour to promote and increase the payment and better the standing of 'Poor-law Medical officers.' In most Unions remuneration for services cannot be worse. The relieving officer appears to have entire control over the Medical officer—whoever makes application he gives an *Order* and frequently when none is wanted. Two cases occurred with me lately, both about nine miles from my residence (of course within my district), and when I visited case No. 1., I found my "patient" working at a mangle. On asking why they requested my services, the mother coolly said the relieving officer asked how they were, her reply was, that the daughter was not very well, and he forthwith gave an order. Case No. 2.—The woman had gone from home two days previous to my visit (her daughter informed me) to help her sister to kill and salt a pig, and would not return until the end of the week. Thus you will observe by the double journey I travelled a distance of thirty-six miles for no purpose. If by your perseverance you can do anything for us in the forthcoming Session of Parliament, the Profession will have great reason to rejoice. If need be I shall not object to a further donation. I may mention that my salary is 30*l.* per annum for a very large district. I am, &c., ——.

MEDICAL STUDENTS.—The returns of the number of gentlemen, now pursuing their professional studies at the metropolitan and provincial hospitals recognised by the Council of the Royal College of Surgeons of England, have now been made to the government inspectors of anatomy (Mr. Charles Hawkins and Dr. Cursham). From these documents it appears, in comparison with those of last year, that notwithstanding the recent stringent regulations requiring a higher standard of preliminary education and examination, there is an increase, instead of the great decrease which had been anticipated from the above cause, in the number of students at the different Medical schools in the United Kingdom. In this metropolis there are at the present time 1,022 registered Medical students at the eleven recognised hospitals, being an increase of forty-one over the number of last session, and no less than 316 are new entries, or first-year's men, representing an increase over the number of last year of seven. At the nine recognised provincial hospitals there are 249 gentlemen pursuing their studies. Curiously enough, this is the exact number at only one of our large metropolitan schools—that of Guy's, where there are upwards of eighty new entries. At the provincial schools there has been an increase of only two over the number of last year. The above numbers do not represent the whole of the students pursuing their studies, as many have omitted or are ineligible to register, not having passed a preliminary examination in arts, &c., in pursuance of the regulations of the Medical Council of Education and Registration. It is also stated that there is a great increase in the number of gentlemen pursuing their studies exclusively for the dental diploma of the Royal College of Surgeons. It is important that the members of a commission, now sitting to inquire into the relative position and the grievances of assistant-surgeons in her Majesty's army and navy, should know that a great number of the metropolitan Medical students now attach the titles of B.A. and M.A., Oxon., Cantab., or Lond., to their names, and that there are many highly qualified gentlemen anxious to enter on the naval and military services of their country if assured of better treatment in the respective services.

WEDNESDAY, DECEMBER 6, 1865.

THE MEDICAL CIRCULAR.

THE HOMŒOPATHIC QUACKS AND THE CATTLE PLAGUE.

The homœopathic quacks have now a splendid opportunity of vindicating their theories from the contempt with which they have been so long and so justly regarded by the Medical Profession. Just as successful rebellion becomes patriotism, and triumphant dissent becomes orthodoxy, so do scientific doctrines, however extravagant or ridiculous they may at first sight appear, become elevated into established truths when they have been ratified by common assent and by the test of experience. It has been very truly asserted that the world did not at first receive the theory of the circulation of the blood or admit the efficacy of vaccination; and the modern science of chemistry and the wonderful developments of steam power may be said to have sprung from a few philosophic experiments by Dr. Black on latent heat, and on fixed air or carbonic acid. So again the brilliant discoveries in electricity and galvanism, with all their train of important consequences to science and art, may be said to have sprung from some apparently insignificant experiments with amber and sealing wax, and with the muscles of a recently dissected frog. Thus, there is nothing more extraordinary in the supposition that diseases should be cured by the same agencies that have produced them, or that infinitesimal doses should cause changes in the living organism, than that a kettlefull of boiling water should set a cotton-mill in action, or that the contact of some metals with an acid solution should be the means of conveying intelligence between the most remote quarters of the globe.

The only difference between the two sets of phenomena is the following:—We *know* that a certain quantity of boiling water will set a steam-engine in action, and that the contact of metals and acid in a galvanic battery will work the electric telegraph; but we do *not* know that a decillionth of a grain of sand or sugar of milk will cause or cure a given disease. One set of facts rests for its authenticity on the researches of scientific men and the common experience of mankind, the other set of alleged facts rests only on the fancies of a German dreamer and the statements of a few persons whose veracity, to say the least, is not yet fully established.

It is admitted that there are difficulties in the investigation of the action of therapeutic agents on human beings, but such difficulties do not exist in the case of brute animals or of inanimate matter. It is obviously cruel to allow a patient to endure the agonies of pain while we are determining whether his sufferings will be allayed by a billionth of a grain of charcoal or flint, when we know, or, at least, believe, that a grain of opium will procure him relief and repose. But such an experiment is quite justifiable in the lower animals, and if an infinitesimal dose of "arse nicum or of "thus" should be found to relieve neuralgia in a monkey, or peritonitis in a cat, we should not grudge the sufferings endured by the animal in the performance of so important a therapeutical experiment. Nay, more, if it should be proved by an adequate number of credible witnesses that the homœopathic drugs in infinitesimal doses did really produce the effects attributed to them, we would become homœopathists ourselves. It is only because the so-called homœopathists have alleged what is not true, and have asserted their power to cure diseases which they know are beyond their skill, that we denounce them as impostors and quacks, and their so-called "system" as a tissue of folly and deception.

It is unnecessary to remind professional readers that legitimate Medicine makes no claim to infallibility. We do not profess to banish disease and death from mankind, or to proclaim a panacea for all diseases. Furthermore, we do not allege that all diseases are to be treated in the same manner or by the same remedies, or even that every disease has a specific remedy. So far from the number of specifics being likely to increase, they are daily diminishing, and we may probably before long see the day when we may have no specifics at all. We fully admit that Holloway's pills are supposed, by a certain portion of the public, to cure all diseases; and another portion has an equal faith in Morison's pills; and still, another portion believes in the efficacy of the homœopathic globules. Now, we are sufficiently catholic in our notions to admit that Holloway's pills, and Morison's pills, and Hahnemann's globules *may* be efficient in certain cases, just as we believe that in some cases a purgative may be necessary, and that in a few cases it is better to give some globules, or, in other words, to do nothing at all. But we utterly and entirely deny that any, or all these forms of quackery are able to do what legitimate Medicine is unable to accomplish, and our incredulity on this point will continue until proof is brought forward to the contrary.

Now is the time for the proof to be adduced. A grievous disease has attacked our oxen, and legitimate Medicine admits its inability to announce any specific remedy for the plague. There is nothing extraordinary in this confession. Disease has swept away the grapes in Madeira, and has also prevailed extensively in the wine-growing districts of Europe. Potatoes have suffered from the occasional visits of a mysterious disease, and a sterilizing blight has periodically visited our hops, our corn-crops, and other forms of vegetation. Science has attempted, with more or less success, to unravel the nature of these epidemics, or rather *epiphytes* and to prevent their recurrence, but science has made no pretence of infallibly effecting cures. But homœopathy arrogantly assumes to do what science, or, indeed, any human power, makes no pretence of effecting, and it is only right that homœopathy should now make good its assumptions. So far from legitimate Medicine, or what is foolishly called *allopathy*, offering any opposition to a trial of the homœopathic system, the fullest opportunities are now afforded for the experiments, which are certainly performed under the most favourable auspices. The leading daily journal

although utterly ignorant of the very groundwork on which Medicine rests, and therefore quite incapable even of understanding the points at present under discussion, is an avowed champion of what we consider the homœopathic delusion, and has therefore the power, by the force of its circulation, to prejudge the question. Here we have some thousands of cattle perishing every week from the attacks of a mysterious but fatal disease, which Medicine professes its inability to cure: homœopathy declares that it can cure. The system of Hahnemann is now therefore fairly before the world: if the globules of "arsenicum" can be shown upon credible evidence to be more efficacious than the "do-nothing" system, we shall as we have before said, be among the first to accept the new doctrine; but if, on the contrary, the homœopathic plan should fail, we shall continue to regard it, as we have hitherto done, as a delusion and a sham.

THE CASE OF ROBERT HUNTER.

Although Robert Hunter has been acquitted, and we believe rightly, of the charge of rape preferred against him, yet there were a few features of the case which have caused some curiosity and have excited some comment in connexion with the proceedings at the Central Crimnal Court, and with the management respectively of the prosecution and the defence. The incidents in question although they appear to manifest a great amount of Old Bailey ingenuity, do not much tend to exalt our notions of criminal law as a British institution. In the first place, it will be remembered that almost immediately after the alleged rape, the ravished lady repaired to the house of a friend, a Mrs. Sharland, to whom, it might be presumed, she related the particulars of the outrage, and who would therefore be a most important witness. But neither on the examination before the magistrate, nor at the trial, was Mrs. Sharland produced, and on the latter occasion it was stated that she had gone into the country. Now surely her evidence was material enough to induce either the prosecution or the defence to require her appearance, and the neglect of both sides to demand her presence, or, for want of it, to request a postponement of the trial, is, to say the least, a very remarkable circumstance. Again, on the examination before the magistrate, Mr. Sleigh, Hunter's advocate, not only insisted upon the great improbability of the story told by the prosecutrix, but he positively asserted that the alleged assault *could not* have been committed, because on the day named, Hunter never saw the prosecutrix at all, and Mr. Sleigh actually called witnesses in support of this statement. These witnesses, some of whom described themselves as registered members of the Medical Profession, completely corroborated Mr. Sleigh's line of defence, and showed most satisfactorily that the prosecutrix did not come to Hunter's house. But on the trial, not only was this line of defence abandoned, but Mr. Sergeant Ballantine, who, in conjunction with Mr. Sleigh, appeared for the accused, not only fully admitted that the prosecutrix *did* visit Hunter on the day named, but he produced a letter written by her to Hunter after the alleged assault, and proving conclusively that she had seen him. Thus we find two barristers (both, too, retained on the same side), one of whom declares before the magistrate that his client never saw his accuser on the day named, and calls witnesses who distinctly swear to the truth of his statement, and the other barrister at the trial drops these same witnesses, and produces a letter conclusively proving that his client *did* see her. Those who regard law as the perfection of reason will perhaps be able to reconcile this apparent anomaly, but as we are Davus, not Œdipus, we confess that the enigma is too much for us. As we believe Hunter intends to prosecute the husband of Mrs. Meyrick, and another person, for an assault upon him, we shall probably hear some more of the story, and in the meantime we leave the facts as they stand to the consideration of the curious.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

TUESDAY, NOV. 14TH, 1865.

Dr. ALDERSON, F.R.S., PRESIDENT.

A paper by Mr. SQUAREY was communicated by Dr. Garrod,

ON THE INFLUENCE OF THE INGESTION OF COFFEE ON THE UREA AND CHLORIDES IN THE URINE.

Observations were made on three cases whilst Mr. Squarey was residing at University College Hospital as physician's assistant. The coffee was taken three times daily, at first in quarter-ounce doses, and gradually increased till in the third case from four to six ounces were taken each day. The temperature in two of the cases was taken night and morning, and was never found to be above or below the limits of health. The urine was collected every morning at eight a.m., and examined the same day for urea and chlorides. Both analyses were made by Liebig's volumetric method.

Urea.

In the first case the observations were carried on for six weeks. The patient's health was good the whole time and he never complained of any uneasy sensation after taking the coffee. It was taken three times daily in quarter-ounce doses every alternate week. On comparing corresponding weeks of coffee and non-coffee taking, no appreciable difference is to be found. The greatest is in the first and second weeks. The daily average in the second week, when quarter-ounce doses of coffee were taken three times each day, was 2·198 grammes more than in the first week when no coffee was taken; in the third and fourth weeks the daily average was less by ·424 of a gramme in the fourth week when coffee was taken; in the fifth and sixth weeks the daily average was less by ·515 of a gramme in the sixth week when no coffee was taken.

In the second case the observations, owing to an attack of tonsilitis supervening, and the patient leaving the hospital immediately on recovery, were only continued for one week, so that the influence of the coffee can only be judged of by comparing the amount of urea passed per kilogramme of body weight with the normal amount in health. The patient's age was seventeen years; his weight was 115 lbs., or 52 kilogrammes; and he passed on the average ·428 of a gramme of urea per kilogramme of body weight. He was taking half-ounce doses of coffee three times daily.

In the third case the observations were carried on for ten weeks. On comparing the first and second weeks, it is found that the daily average was greater in the second, when three cups of a strong infusion of coffee were taken three times each day, by ·381 of a gramme. On comparing the third and fourth weeks, a great diminution is found in the daily average of the latter, when quarter-ounce doses of coffee were taken three times daily; it was less by 5·099 grammes. Yet in the fifth week, when the same amount of coffee was taken, and in the seventh week, when half an ounce was taken twice a day, and in the eighth week, when half an ounce was taken three times a day, the daily average was greater than in the sixth, when no coffee was taken; so that, although the daily average was lessened one week when quarter-ounce doses of coffee were taken, yet it did not rise when the coffee was left off, or become again diminished when the same and even larger doses were taken. The daily average in the ninth week, when from one and a half to six ounces of coffee were taken each day, was less by 4·795 grammes than in the tenth week, when no coffee was taken; but in the tenth week, the patient not feeling well, the diet, which up to this time had been very strict, was varied, his health and appetite improved, and with it there was naturally a daily increase in the excretion of urea.

From these results, Mr. Squarey argues that coffee in the above doses certainly does not increase the excretion of urea, or diminish it to any appreciable extent; for he says that the slight difference that occurred in the daily average of the six consecutive weeks in the first case was by no means

beyond the limits of health. That in the second case the amount of urea excreted per kilogramme of body weight was quite normal. That although in the third case there was the large diminution of five grammes in the daily average of the fourth week, when coffee was taken, yet this diminution did not recur when the same and even larger doses were taken; nor did the daily average rise when the coffee was left off, which it should have done had the decrease been entirely due to the influence of the coffee. That, according to Dr. Parkes, in his book on the Urine, page 8, says that "the maximum and minimum amounts of urea passed on any one day by an individual are usually about one-fifth above and below his mean amount;" so that in the third case, the patient passing on the average between thirty and thirty-five grammes, an increase or diminution of six grammes would be within the normal limits.

Chlorides.

In the first case the daily average of the two weeks when coffee was taken in quarter-ounce doses was as nearly as possible the same as in the two corresponding weeks when no coffee was taken; the amount excreted per kilogramme of body weight being quite normal.

In the second case, half-ounce doses of coffee being taken three times daily, the amount of chlorides excreted per kilogramme of body weight was ·162 of a gramme—a rather large, but certainly not abnormal proportion for a boy aged seventeen, and weighing 52 kilogrammes.

In the third case the rate of excretion of the chlorides was high throughout the whole course of the observations, both during the coffee taking and the non-coffee taking weeks. The amount excreted per kilogramme of body weight was highest in the seventh week, ·272 of a gramme, when half-ounce doses of coffee were taken twice daily; and lowest in the eighth week, ·168 of a gramme, when half-ounce doses were taken three times each day.

In conclusion, Mr. Squarey states that neither of the patients suffered in any way from ill-effects from taking the coffee. There was never any giddiness, delirium, or unsteadiness of the hands. The patients invariably slept well.

The pulse, noted several times, was generally found to be increased for half an hour or so after taking the coffee.

The PRESIDENT spoke in terms of commendation of the large and patient observation in the author's paper. There were, however, several points in it on which further information was required. In the first place, it was necessary to know more exactly what kind of coffee was used—whether it was Plantation or Mocha, and whether, if it had been bought ground, it had not been adulterated. Again, the amount of exercise taken during the experiments would affect their results considerably. The effect of muscular activity in increasing the amount of urea was shown by its increase in chorea. Coffee would sometimes constipate, and at others would act as an aperient.

Dr. WEBSTER said that what was often sold as coffee might scarcely be coffee, but chicory. His object, however, in rising was to remark, with great submission, that he could scarcely understand the paper. This was not due to any fault in the Secretary's reading, but to using of French names for weights which required calculation. He had, he remarked, protested before against this, and still thought that English words ought to be used before an English society. He thought also the subject should be studied on a more extensive scale, and suggested to the author to inquire more widely into the effects of coffee-drinking. To do this, he had only to go across the Channel to France, and then to Spain, where no coffee was drunk, but only chocolate.

Mr. WILLIAM DUNN read some

OBSERVATIONS ON THE TREATMENT OF HEREDITARY SYPHILIS; WITH CASES TREATED WITHOUT MERCURY.

(*Communicated by* Robert Dunn, F.R.C.S.)

The author first narrated the particulars of some cases of hereditary syphilis which had come under his observation at the Farringdon Dispensary, and which he had successfully treated with chlorate of potash, without using mercury in any form whatever. Out of fifty cases which he had thus treated, he had met with only one case of relapse, which readily yielded to a repetition of the same treatment, and three deaths, one child dying of convulsions, and the other two being in a dying state when first seen by him. The author then entered upon the general treament of syphilis, briefly alluding to and giving the names of those who have advocated the non-mercurial treatment. On the authority of the 'British and Foreign Medico-Chirurgical Review,' he stated that from 1800 to 1835 about eighty thousand cases of syphilis had been treated without mercury. He rejoiced in the belief that the non-mercurial treatment was gaining ground amongst the Profession; and owing to having been so often disappointed himself in the results of specific treatment, he had now abandoned completely the use of mercury in any form in the general treatment of syphilis. In the treatment of hereditary syphilis, he considered that we must be guided by the same general rules which we observe in treating other diseases. All remedies of a depressing or lowering character ought to be avoided; and, on the other hand, tonics, cod-liver oil, strict diet, and extreme cleanliness, were essential to successful treatment. He bore evidence to the marvellous effects upon children of chlorate of potash in combination with hydrochloric acid in this disease. Where the skin was very irritable, he recommended a bran bath, the bowels to be carefully regulated, and the child to be out in the pure air as much as possible. Sixty-three days was the longest period any child had been under his treatment, and eighteen days was the shortest, the average time being about thirty days.

MR. HENRY LEE said that if the experience of other practitioners confirmed the results mentioned by Mr. Dunn, it would leave nothing to be desired with regard to the treatment of syphilis. Unfortunately, however, such was not the case. Out of the number of instances that Mr. Dunn had referred to, a relapse occurred in one case only; and the death-rate of infantile syphilis was as low as 6 per cent. These results proved too much. They were altogether at variance with the experience of those who treated this disease either with or without mercury. Thus, for instance, we were informed in Professor Boeck's published work that out of forty-two children treated by him without mercury, twenty-two died; and these cases were independent of those who died without undergoing the process of treatment recommended by Dr. Boeck. Some rational explanation must therefore be sought for the great difference observed in Mr. Dunn's cases, and where the history of the patients could be traced for a longer period; and this he (Mr. Lee) believed would be found in the fact that in dispensary practice, when mothers found their children not progressing satisfactorily, they took them elsewhere, and in cases of relapse after treatment, they would naturally feel inclined to try some other remedy. If the cases thus abstracted from observation were recorded as cures, it would be the means of affording very favourable statistical returns under any mode of treatment. With regard to the treatment of syphilis generally, it constantly happened to him (Mr. Lee) to have patients who presented themselves after four or five years of non-mercurial treatment still uncured, and regretting that they had lost so much time in fruitless attempts to obtain relief; and he also not unfrequently saw some very severe secondary symptoms after the non-mercurial plan of treatment. Indeed, some of the worst cases of secondary sloughing of the throat and of disease of the bones which he had seen occurred amongst those in which no mercury had been used. He therefore thought that, although mercury might be injudiciously given and might then produce injurious effects, the ill consequences attributed to it in reality very often indeed depended upon other causes. We had now the means of administering this remedy without making any serious demand upon the constitutional powers; and when thus administered with proper care, it was a most valuable remedy, and certainly not followed by the symptoms which had been attributed to it. The author of the paper had alluded to the effect of the mother's milk upon a child. Now he (Mr. Lee) did not believe that any

poisonous influence could be conveyed in this way. The health of the mother might be impaired by syphilis, and the milk would become poor in consequence, and the child might be ill-nourished; but this was quite a different thing from the transmission of the syphilitic poison by the milk. It was a law with regard to syphilis, that a person having that disease could with great difficulty, under any circumstances, be again infected. The child of a syphilitic mother would in all probability be itself syphilitic, and it would then be very difficult to conceive that any fresh poison could be conveyed to it. But we had proof that even a healthy child would not be affected in this way. The following case had come under his (Mr. Lee's) observation in St. George's Hospital. The patient was admitted during the summer of last year, She had had two healthy children, the youngest eight months old. She and her husband had been healthy. After her last confinement she took another child to nurse. This child proved to be syphilitic, and died three weeks before the patient's admission into the hospital. Shortly after taking this child to nurse she noticed a sore on the right nipple, which became very hard all round. Six weeks before her admission, this patient had an eruption, presenting all the characters of syphilis, over the body, and her throat became ulcerated. During these six weeks she continued to suckle her own child as she had previously done. She, however, always kept her own child to the left breast and the other child to the right one. Her child remained perfectly well during the time she continued in the hospital, and was known to have been so in the November following. This patient had recently been confined again, and was attended from St. George's Hospital; and he (Mr. Lee) had reason to believe that the child which she suckled in the summer of 1864 remained healthy at the present time.

Dr. DRYSDALE said he was sorry to think that the respected Professor Boeck was absent that evening, as he had believed that Dr. Water's paper was to be read, for he doubtless would have been able to answer Mr. Henry Lee's question. In his absence he (Dr. Drysdale) would endeavour to give an answer. It must be remembered that the cases mentioned by the Professor in his work included many infants of but a day or two old. Now, in his own experience, such cases were almost uniformly fatal, for children who were much affected by this complaint at birth were often too feeble to breathe; but the cases brought forward by Mr. Dunn were not in this category. Infants were not brought to an hospital by their mothers until they were three or four weeks old, and all of the cases cited by Mr. Dunn were of that age. It was a great and, he thought, rather prevalent error to imagine that all syphilitic children were emaciated and cachectic. Many of them were plump and well nourished; and the old-man look was rather the exception than the rule. There was then nothing surprising in Mr. Dunn's success with the care he had taken of the cases, many of which he (Dr. Drysdale) had seen. The wonder was that these cases should so long have been considered to require a dangerous drug like mercury; he himself, he believed, having been the first to publish a case of infantile syphilis treated without mercury. These facts completed the chain of evidence against mercury in syphilis, since it had been shown by experience of the most extensive kind that the disease in adults was always injured by the drug instead of being alleviated. Bone disease, if it occurred without mercury, was very rare, since Syme, Weedon Cooke, and Spencer Wells had not *seen* cases. In fact, the empirical school of treatment of disease was losing its hold on many of the Profession, and a six months' course of mercury to cure a blood poison would soon be considered an absurdity. Parents much mercurialized were liable to syphilitic children far more than others.

Mr. GEORGE COOPER had seen a large number of cases of infantile syphilis at the Bloomsbury Dispensary, and had nearly always treated them with mercury. In some cases he had tried iodide of potassium, but had always been obliged to fall back on hydrargyrum c. creti. With the latter treatment he had found the symptoms would generally yield, and that the child would improve. He thought the author's remark as to the effect of the mother's milk quite right. He thought the milk did communicate the disease, and that it continued to do so. Hence he had recommended that the child should be weaned, and be fed on cow's milk and, if necessary, on beef-tea.

Mr. SAVORY said: In the course of his remarks, Dr. Drysdale has repeated a statement which he made on a former occasion—to the effect that surgeons treated syphilis empirically with mercury, because they had never tried to cure it by any other means. It could not be admitted that this statement was correct. On the contrary, a very large number of cases of syphilis have been, and still are, treated by many surgeons without any mercury whatever. I appeal to the Fellows present whether this be not so. The treatment of syphilis without mercury is surely no novelty. For myself, I may say that, during the earlier years of my professional studies, I watched the practice of more than one surgeon who treated almost every case of syphilis without mercury, not employing the drug once in a hundred instances; and the result of these observations, compared with subsequent ones, was to lead me to the conclusion that no medicine is comparable with mercury for controlling the progress of syphilis. In such discussions as this, the fact seems to be altogether overlooked that there is such a thing as the natural history of disease. Syphilis does not, more than any other disease, stand still and wait for the doctor. Syphilis is the result of a poison, and, like other poisons, its operation, sooner or later, comes to an end. All poisons acting upon the animal body tend, so far as we know, either to destroy life, or finally to be eliminated from the system; and there is no reason to believe that syphilis is an exception. Syphilis, as a rule, does not tend to kill, but gradually to die out of—to lose its influence on the system; very gradually, it is true, inasmuch as we possess but too abundant evidence to show that it may be carried on under the second, or even third, generation. But then it must not be forgotten that time is most important in modifying or subduing its potency; for, as a rule, it may, perhaps, be said that in proportion to the duration of syphilis so is the activity of the poison reduced; and thus when we treat hereditary, or, as it should rather be called, inherited syphilis, we have a very different condition to cope with from syphilis as it appears soon after inoculation. Thus, in looking over the literature of syphilis, one can observe that various drugs are reputed to possess a more remarkable influence over syphilis in proportion to the length of time it has existed in the body. Iodide of potassium, for instance, is put forth by Gross and others as an efficient remedy for the removal of the later symptoms of constitutional syphilis. In illustration that this fact is too often overlooked, I would refer to what has just fallen from Mr. Lee, who, in reply to Mr. Dunn's statement that hereditary syphilis in infants may be cured by chlorate of potash, quoted the fact that mercury alone had the power of completely curing recently contracted syphilis in the adult. But the conditions are different. Syphilis may, at length, finally disappear under, or appear to succumb to, the employment of means which are powerless to control if in the earlier stages of its progress. The influence of syphilis, mischievous and enduring as it is, cannot run on for ever. It naturally tends to pass away in the course of time.

Mr. SPENCER WELLS asked the author if he thought the administration of small doses of chlorate of potash had any sort of effect. Recently Dr. Gull and Dr. Sutton had published cases of rheumatic fever treated by mint water. This would do good only by amusing the patient, and perhaps the chlorate of potash might be useful by amusing the mother of the syphilitic infant, It would be very interesting to observe the comparative effects of chlorate of potash and some completely neutral drug.

Mr. DUNN, in his reply, said that he had faith in the curative effect of chlorate of potash in the treatment of hereditary syphilis. As regards the question of relapse, he had only met with one case in his own practice, and one in the practice of Mr. Allingham; in the latter case the child had twice returned to the dispensary with syphilitic ulcer of the anus. His (Mr. Dunn's) patients, when they

left off attending at the dispensary, were certainly cured; but he could not say whether they had a relapse or not, for they might have gone to some other institution to be treated. He certainly considered it a most important point in the treatment of the disease that the child should not be suckled by the milk of a syphilitic mother. If the milk does not convey the poison to the child, it must be in an impoverished condition. He mentioned the following case, in which he thought the child must have been poisoned by the syphilitic milk of the nurse:—A child, born of healthy parents, was put out to nurse; the nurse, being syphilitic, had no ulcerations of the breast, but syphilitic alopecia and sore-throat. The child soon showed signs of the disease, and was treated by mercury, and died. The mother has been confined since of a healthy child, which she nursed herself. This child is quite well and healthy, and has not shown any signs of the disease. He also stated that Mr. Whitehead, in his work on 'Hereditary Disease,' mentions cases proving the same fact.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 7TH, 1865.

DR. PEACOCK, PRESIDENT.

MR. SPENCER WELLS exhibited an

ENLARGED SPLEEN REMOVED BY INCISION.

the day before the meeting. The patient was going on tolerably well when Mr. Wells saw her (thirty hours after operation) on his way to the meeting. When removed it weighed six lbs. five ounces, but as nine ounces of blood had drained from its vessels, it now weighed five lbs. twelve ounces. It was eleven inches long, eight broad, and three to four thick. It appeared to be simply hypertrophied, though some spots on the surface appeared like commencing amyloid or lardaceous change. It was not cut into, however, as, being the first case in which the operation had been done in this country, it was to be sent to the Museum of the College of Surgeons. Mr. Wells added, that when Mr. Nunn showed a large spleen in that room two or three years ago, and he (Mr. Wells) had suggested that the patient's life might probably have been saved if the spleen had been removed, Dr. Wilks had approved of the suggestion, and he (Mr. Wells) determined to try what could be done if he met with a suitable case. Soon afterwards he attended a lady, with Dr. Jenner, who had a very large spleen; but there was such extreme leukhæmia co-existing that operation was never seriously thought of. The lady died near Bristol, and Mr. Clarke, of Clifton, who examined the body, was specially requested to do so with reference to the removal of the spleen. He informed Mr. Wells that it was done quite easily, and that, in his opinion, all the blood-vessels might have been easily secured. Mr. Wells afterwards saw cases of enlarged spleen with Dr. Rudd, Dr. Boulton, of Horncastle, and Dr. Gill, of Bow; but in these cases they were the result of intermittent fever, and not in a state of health to render a hazardous operation necessary or justifiable. At length the patient whose spleen was before the Society consulted him six weeks ago. She was married, 34 years of age, and the mother of two children. She had only been ill about a year, and the tumour had only been discovered six months. Its growth had been slow at first, but very rapid lately. Mr. Wells prescribed bromide of potassium and quinine. This proving useless, iron was given; and this being equally useless, excision was proposed, and Dr. Jenner consulted, who said she was dying, that medicine could do no good, while an operation did offer the "*shadow of a chance*" of success. Upon this the patient and her husband desired that the trial should be made. Mr. Wells found the operation quite easy. An incision, seven inches long, was carried along the outer border of the left rectus abdominis, and the spleen was turned out very easily. The vessels were secured by silk ligatures, which were cut off short and returned. There was very little bleeding. The patient had recovered from the shock, there were as yet no signs of peritonitis; and, if she should recover from the operation, all that we know of removal of the healthy spleen in dogs, and in man accidentally by wounds, led to the hope that the absence of the spleen might be tolerated and a good state of health regained.

Dr. CRISP said the case was a very interesting one, but he did not think it was parallel with cases of removal of spleen from dogs. He had, he said, never seen a healthy liver with such a spleen. He thought the liver had more to do with blood formation than the spleen had.

Dr. GIBB had once removed a spleen weighing many pounds from a dog. The enlargement had followed an injury. The dog died in a few days of peritonitis, having been exposed to cold.

Dr. GREENHOW asked Mr. Spencer Wells what was the nature of the hypertrophy of the spleen. This was, he thought, an important question as regards the probability of recovery from such an operation.

Mr. SPENCER WELLS said he should present the specimen to the College of Surgeons, and he had no doubt that Mr. Flower would make a full report.

Dr. CRISP referred again to the specimen, and said there was a kind of enlarged spleen which had not yet been described—viz., that caused by violence. He had no doubt but that in Dr. Gibb's dog the spleen had enlarged from this cause. Dr. Crisp then referred to a specimen in St. Thomas's Hospital in which the enlargement seemed to have been caused by injury, and also to another case in which it came on after a confinement.

Mr. SPENCER WELLS said there was no history of any hurt in his patient's case. It did date from the birth of a child, although it was several months after the abdomen had been observed to be enlarged.

Dr. GIBB said that a kick had been the cause of the enlargement in the dog's spleen, and blood was found under the capsule on removal.

Mr. NUNNELEY, of Leeds, showed a specimen of

BLACK CATARACT.

The patient, seventy-five years of age, had had double cataract. Nothing unusual had been observed in the case. The right lens, which had been the longer affected, was extracted January 19, 1865. It was then quite black at the centre, and nearly so at the margin, but it had become of a lighter colour by keeping. The other lens was extracted in February, and was of a lighter colour, and was also of a lower specific gravity.

Mr. NUNNELEY also showed

FOUR OVARIAN TUMOURS WHICH HAD BEEN REMOVED BY OVARIOTOMY.

The following is his report of them:—

No. 1 tumour was taken from a married woman, aged thirty-six, whose case had been mistaken for, and treated as, ascites, until she was very weak and exhausted. She had been delivered of a child a few months previously. On the nature of the case being explained to her, and the danger of the operation, she was very wishful to have it performed. There was literally universal adhesion of the sac in every direction. When it was punctured with the trochar, the contents were as solid as thick jelly, and would not pass through the tube. A long incision was made into the tumour, other contents were removed with the hand, but it was impossible to detach the sac; the abdominal wound was therefore closed. The woman died twenty-two hours afterwards. Even after death the sac could not be detached, except by tearing through the whole peritoneal surface, which is now seen adhering to the thick walls of the sac. No. 2 was removed from an unmarried woman (one of the largest women I ever saw), aged twenty-six, but who had had one child at the full term, and a miscarriage at the fifth month, when doubtless the ovarian disease had been developed. She had suffered much from distension, and had a good deal of abdominal pain, which induced suspicion of the existence of adhesions. These were found to exist to a considerable degree to the peritoneum, to the omentum, and in a less degree to the intestines. There was very little peritoneal fluid. The tumour sprang from the right ovary, and had a moderately long pedicle. It was tied with China twist, and secured with

one of the uniting pins. The wound healed without any trouble, though for three days there was much distressing sickness; when this abated, the woman rapidly recovered. Six months after the operation she married, and at once became pregnant, and was delivered of a very large child. She has since remained well. No. 3 tumour, which is solid, was removed from a single woman aged forty-three. It had existed three years. She had been tapped once. There were twenty pints of thick peritoneal fluid. The tumour sprang from the right ovary. There were no adhesions. The pedicle, a moderately long one, was tied with China twist, and included with one of the hare-lip pins which closed the wound. Four of these pins were employed and passed through the peritoneum with small cutaneous wire sutures between. The wound united by first intention; the ligature came away on the eighteenth day. The woman never had a bad symptom; she was up in twelve days, and was walking in the street in less than three weeks. She continues well. No. 4 was removed from a married woman forty-five years of age. She had had two children upwards of twenty years before. The disease had existed several years. In her there were seventeen pints of thick peritoneal fluid. The tumour consisted of the right ovary converted into a mass of small cells, which are so closely bound together as to constitute a solid globular mass weighing six pounds. The pedicle, which was very short, consisted of the broad ligament, spread out to seven inches in breadth, and so short that there was no room to place a ligature securely on it. The hot iron was used with great advantage. A ligature of China twist was also left on it close to the uterus; this was left *in situ* in the pelvis. The wound was secured by three large pins and twisted sutures (the peritoneum being well included) and intervening cutaneous stitches. The wound united by first intention; she was up on the twelth day, and on the fourteenth was removed to a distance in a cab, as her nurse was seized with idiopathic erysipelas. The ligature came away on the twentieth day. She was well from the first. To these two women Dutch liquid (the chloride of olefiant gas) was administered as an anæsthetic.

Mr. NUNNELEY then showed

TWO OVARIAN TUMOURS REMOVED FROM ONE PATIENT.

The two smaller tumours are, he believed, instances of malignant disease of the ovaries. They were taken from a woman, who had been married several years, but had not been pregnant; her health had not been good for a long time past. There was no suspicion of the existence of malignant disease. She was a very large size, owing to the quantity of peritoneal fluid—indeed, so great that as it flowed out and the parietes collapsed, some who witnessed the operation were disposed to suspect a mistake in the diagnosis had been made. However, both ovaries were found to be involved, and were removed. When taken out of the body, the tumours had the appearance of masses of half-boiled sago. The pedicles were so short as to be with very great difficulty secured. The woman never rallied from the operation; intense and constant sickness continued; she died on the third day. On post-mortem, a small quantity of blood (perhaps one-third of an ounce) was found in the pelvis, which must have escaped from one of the pedicles, though the ligature on both appeared to be tightly fixed, it was probably caused by the constant strain of vomiting. There was some diffuse inflammation of the peritoneum.

Mr. NUNNELEY also exhibited

AN ENTIRE TONGUE SUCCESSFULLY REMOVED DURING LIFE.

The entire tongue had been removed, on the 2nd of this month, from a man, aged thirty-five, by a submental opening. He never had a bad symptom, and is now quite well. The disease, which had existed sixteen or eighteen months, became worse two months before the operation, and from the pain and difficulty of speaking, the impossibility of mastication, and difficulty of deglutition, was fast wearing the patient out. He has already recovered strength and flesh; indeed, he says that he is as well as he ever was. Talks with great distinctness and swallows with facility.

Mr. SPENCER WELLS thought that one of the specimens was not one of an ovarian tumour, but a fibrous outgrowth of the uterus.

The specimen was, therefore, referred to a Committee.

Mr. NUNNELEY said, in reply to Mr. Barwell, that the patient whose case he had related in a paper read before the Medical and Chirurgical Society remained well for twelve months and then died of Consumption. It was remarkable that both of these patients could talk well, in spite of the removal of their tongues.

Several specimens were exhibited by Dr. Crisp, Dr Tilbury Fox, Mr. Barwell, &c., a report of which will appear next week.

PARISIAN MEDICAL NEWS.

THE CHOLERA.

In the presence of a scourge, which invades alike all nations, and oversteps every frontier, the great hygienic measures, adopted by the different governments with a view of preventing its recurrence, should be received with feelings of gratitude; and on the scientific press more especially devolves the duty of recording the acts suggestive of such measures, were it only as an encouragement to further exertion, and for the purpose of taking note of all the documents calculated to throw light on the epidemics to which they refer.

On the subject of the nature of the measures which it may be deemed useful or practicable to adopt for the purpose of preventing the return of cholera, we can only form mere conjectures; but the plan of an international sanitary conference entrusted with the duty of instituting an inquiry on the subject has received the approbation of almost every government; and, as it is observed in a letter from Rome, published in the 'Moniteur du Soir,' the plan proposed touched too nearly the interests of humanity not to be hailed by unanimous assent.

We can add nothing to what is already well known as to the course followed by the epidemic in its progress towards Paris. Cholera may be an inoculable, or properly speaking a contagious disease, but it is unquestionably infectious. It may, therefore, not unreasonably be argued that the scourge which now again visits the capital may chiefly have been brought by waggons laden with goods at Marseilles, and forwarded by rail from the Lyons to the Western terminus, in the warehouses of which they were opened. This would account for the first appearance of the disease in the 17th and 18th arrondissements, in which it appeared at first to be confined, but whence it has since extended over the entire city and some of the adjacent boroughs.

From the 1st to the 15th of October, the epidemic has steadily gained ground in Paris, thus contradicting all the reassuring predictions of certain optimist journals, which, like Florian's parrot, each morning repeated, "*It will be nothing.*" The returns from the hospitals are now, it is true, more satisfactory, but this is referable to the fact that many mild cases are at present admitted into the wards, in a less advanced stage of the disease than at first; but in the city the mortality has unceasingly increased, and, as in former epidemics, from the destitute the evil has ascended to a higher class of persons, who have, however, not yet numbered many victims.

The decrease of the mortality from cholera set in on the 20th, and up to the present date the improvement has steadily continued, although several districts still suffer severely.

We must not omit to remark that by far the greater number of the victims are persons who for several days had suffered from diarrhœa, or were weakened by some accidental cause. In the 'Quartier St. Georges,' which we reside in, the removals of the 8th of October, the quarter day for small tenants, have exercised some influence on the symptoms in several instances. These removals, from a sixth flat to another equally high floor in another house, necessarily entail on an entire family considerable, although transient, fatigue, privations, and change of diet. The conveyance of the poor furniture is performed piecemeal and requires numerous journeys to and fro; the men drink, the

women suffer, and as no cooking is practicable, pork-butchers' meat, or other improper food is consumed, and if an epidemic is prevalent, it finds a soil ready prepared for its development. Here, as ever, the terrible law *væ victis* finds constant application. We cannot assert that the weak only are liable to cholera; for it carries off numerous vigorous individuals, but it chiefly attacks those who are weakened —a condition which may suddenly and temporarily occur even in the most athletic subjects. Without, therefore, entirely agreeing in every item of the doctrine propounded by M. Jules Guérin, we assent to the practical inferences he deduces from them. Whether the diarrhœa be, as he professes, a milder form of cholera, which we are inclined to doubt, or is merely like over-exertion, sorrow, sexual indulgence, &c., a cause of exhaustion which predisposes the system to the manifestation of the epidemic, we conceive it is desirable to check the intestinal exudation, especially when it assumes a serous or watery aspect.

Several communications, reproduced in the present number, dwell on the premonitory symptoms of cholera, and in our report of the transactions of learned societies, our readers will find the new arguments adduced by M. Jules Guérin in support of his favourite theme. The subject being still *sub judice*, we likewise invite notice to statistical returns of an opposite tendency. M. Guérin's views will, however, meet with no contradiction on one point, viz., the more or less marked influence of the epidemic on the greater part of the population.

In the last impresion of the 'Gazette Médicale,' M. Guérin sagaciously remarks that even before diarrhœa sets in, preliminary symptoms are observed entirely distinct from the nervous agitation, traceable as much to alarm as to the influence of the morbid principle on the system. They consist in something more tangible, and affect equally persons who are fearless, and those whose thoughts incessantly dwell on the chances of infection. The premonitory signs alluded to consist in a kind of torpor and disteusion of the abdominal viscera, accompanied by a sensation of local uneasiness, especially after meals and during the progress of intestinal digestion. The alimentary bolus would seem to meet with some unusual impediment to its progress, and with a morbid condition of the organs, which recurs after ceasing for a time. This state is obviously connected with the choleraic influence, and coincides with very slight cramps, and a transient feeling of nausea; it invariably precedes and gives notice of the approach of diarrhœa. Few individuals, says M. Guérin, are entirely free from these symptoms.

If we were in possession of sufficiently delicate instruments of investigation, and enabled, for instance, to study the minute elements in which epidemics originate with the degree of precision afforded by the microscope for the inspection of minute particles of matter, we should doubtless soon acquire the proof that not a single individual altogether escapes the operation of the deleterious atmosphere we inhale.

The remedy suggested by M. Guérin for the morbid condition here pointed out is the exhibition of charcoal. The flatulency and abdominal disturbances are promptly dispelled by this substance, which may be taken in the shape of lozenges (three or four daily before meals). M. Guérin proposes the following simple explanation of the good effects of the remedy. The charcoal acts as a disinfectant, and neutralises the evil influence of the poison; twenty-four hours after the administration of the lozenges the motions acquire a homogenous black colour, and are almost entirely *inodorous*, a fact which the learned Professor dwells on as important and suggestive.

If diarrhœa supervenes, it should, of course, be checked, but it would be a mistake to suppose, although such is the opinion entertained by M. Guérin, that the chances of cholera are absolutely averted, because the premonitory intestinal relaxation has been successfully arrested. The assertion is unhappily disproved by too large a number of facts, in which it plainly appears that death in cholera is not the result of mere loss of serum. In these almost desperate cases, ammonia, emetics, electricity, and even depletion, advocated by M. Gendrin, sometimes restore the power of absorption and rescue the patients from their apparently inevitable fate.

Of the manifold formulas forwarded from all directions, all, of course, warranted to effect a cure in most cases, we need say little; we shall merely record a very few, but the large number of these nostrums shows that the specific remedy for cholera has still to be discovered, and that we cannot yet boast of a system of treatment applicable to the disease in general. In this respect, learned professors are on a par with the humblest practitioners, and the most eminent of the members of the Academy has recently explained in a few quaint words the silence of the Institute on the subject. We reproduce his remarks from the pages of the 'Union Médicale:'—

"M. Velpeau," says M. Maximin Legrand, in his report of a recent meeting of the Academy of Sciences, "had laid several new works on the table; he had presented a volume on 'Iodotherapy,' by M. Boinet; another on chalazium and tumours of the eyelids, by Professor De Luca, of Naples; a memoir, by M. Brochard, on the mode of propagation of cholera, in which the author, from his experience of the epidemic in 1849, pronounces the disease to be contagious; he had also presented a pamphlet in English by M. Jennery, in which that gentleman expresses his conviction that a cure of cholera can invariably be effected with camphor powder and 'the aromatic confection of the British Pharmacopœia.' M. Velpeau took this opportunity of reminding his audience that in 1832 camphor was considered an infallible remedy, and yet had proved utterly inefficacious to arrest the progress of the scourge.

"Other communications, to which we shall presently advert, had already been made on the same subject, when M. Le Verrier rose to address the chair.

"The learned director of the Observatory of Paris apologised in the first place for his boldness in speaking on a subject with which he was not familiar. He had been much gratified by the intelligence that it was intended to attack the causes of cholera at its point of departure; this was, of course, satisfactory, but would require time; the enemy, however, being actually within our walls, it would be desirable to know exactly how the disease is at present to be contended with, without prejudice to future sanitary operations. All the remedies suggested seem to be tabooed by the Medical Profession, and he wished to know if any were deserving of confidence.

"M. Coste has proposed sanitary measures, and recently pointed out researches which ought to be made. Had I been present on that occasion, said M. Le Verrier, I should assuredly have approved of the latter, and voted for the former. This, however, does not give us the information we require; Medical men are probably engaged in this important inquiry, but they keep their own counsel, and we know nothing of their investigations, on which they maintain a most discouraging silence. They should, in the first place, teach us what is to be done in the event of an attack of cholera. What measure should be resorted to before a Medical man can be summoned? The daily papers supply us, it is true, with a few formulas, perhaps a dozen; but they all differ from each other; which is the best?

"During this address, a member of the Academy, who also happens to be the director of one of the largest government institutions, glided out of the room, audibly murmuring as he passed the reporters bench, 'I must be gone. All this talk about cholera will at last give it to us.'

"M. Le Verrier concluded by adjuring those who are acquainted with the truth as to the present epidemic, to communicate it without any reservation.

"M. Velpeau replied, and the following is the sense, if not the verbal reproduction of his observations.

"I have but little to say in reply to M. Le Verrier. Our colleague is desirous that we should point out the remedies most useful in cholera. It is easy to put such a question, but difficult to indicate any method of treatment of absolutely reliable efficacy; it would be dangerous to allow the public to indulge in a deceptive security in remedial agents of doubtful power.

"The failure of the various medications advocated is attributable to a grievous mistake of the public, and even

of Professional men, who are under the impression that diseases are not susceptible of a spontaneous cure. Many affections yield without treatment, and it must be acknowledged, sometimes, in spite of all treatment. To this fact we must not be wilfully blind. An opposite opinion, however, unfortunately prevails, and every person has a pet remedy for every disease, and every one thinks himself competent to advise. The same remark was already made long ago to Louis XIV. by his physician Fagon : 'Yes,' said the King, 'everyone gives advice in these matters but myself.' Fagon's royal client was not fond of contradiction, even from his doctor, who on this occasion made no reply. A few days after, he appeared before the King with his face bandaged up. 'What is the matter with you?' inquired Louis XIV. 'Nothing please your Majesty,' said Fagon, but a mere swelled face.' 'You must get well,' answered the king, 'I know a capital remedy for such ailments.' . . . 'You perceive, Sire, that you also sometimes venture on giving Medical advice.'

"Every person, therefore, has his own favourite remedy. In general, and in the case of trifling affections, this is a matter of no importance; not so, however, in the case of cholera, which destroys life in a few hours. After the exhibition of a remedy, the symptoms have yielded once, twice, thrice, or oftener; hence it is inferred that the cure has been the consequence of the treatment. The inference is a natural one, but almost invariably incorrect.

"Cholera, like other diseases, does not always end fatally; death follows in about one-half only, even of the worst cases. In all the visitations of this epidemic, a host of different remedies have been resorted to, hence arises a degree of confusion in which neither the public nor the Medical Profession have been enabled to discriminate the share in the issue of the treatment adopted, of the disease itself or of other intervening causes.

"In 1832, as M. Serres will remember, a great variety of medications was instituted at La Pitié for cholera. The result was occasionally favourable, and sometimes the reverse, but it was always impossible to account for the different effects produced by the same medicines.

"When an epidemic exists, I may parenthetically remark, that it is but fair to make allowance for deaths from different causes, which are all placed to the account of the prevalent disease.

"With regard to premonitory symptoms, we may say that they are present in many, but not in all instances of cholera. Too often the disease breaks out without previous notice, and causes death in a few hours.

"Hygienic precautions are the best safeguard; whoever lives *wisely*, will seldom suffer from cholera.

"As to the most trustworthy remedies, I conceive that if colic and nausea supervene, the patient should swallow three or four drops of laudanum poured over a lump of sugar moistened in water. In general this very simple plan arrests the further progress of the symptoms; in the contrary case, a larger quantity of laudanum should be exhibited, and several enemas of bran water containing ten drops of laudanum should be taken in the course of the day. When the attack assumes a more serious form, and vomiting sets in, the patient must be considered in great peril, because the remedies introduced into the stomach are no longer absorbed, and become perfectly useless. External measures of treatment must now be resorted to, such as frictions, hot blankets, &c., very insufficient defences against so formidable an enemy. This, however, is the sad truth, and cannot be altered by idle lamentations."

M. Velpeau's remarks afforded slender comfort to the learned astronomer, but should not be interpreted as an absolute negation of the power of Medical interposition in cholera. Although the pathology of this disease is still an unsolved problem, clinical observation informs us of its effects on the system, and in many cases suggests the remedies best calculated to assist the efforts of nature. M. Velpeau, who is a most sagacious observer, is not slow to take advantage of every opportunity in which interference offers a chance of success, and does not remain inactive in cases of cholera. It was our intention to advert in the concluding part of the present article to the transactions of the Medical Congress at Bordeaux; but the question of cholera is at present of paramount importance, and must take precedence over all others.—'Journal of Practical Medicine and Surgery' for November.

MEDICAL NEWS.

UNIVERSITY INTELLIGENCE.—UNIVERSITY OF LONDON.—Second M.B. Examination, 1865.—*Pass Examination.*—*First Division.*—Bryan Holme Allen, University College; Thomas Bond, Kings's College; Alexander Bruce, University College; Peter Maury Deas, University of Edinburgh; George Wallington Grabham, St. Thomas's Hospital; Charles Augustus Greaves, St. Thomas's Hospital; Thomas Henry Green, University College; William George Vawdry Lush, St. Bartholomew's Hospital; Arthur George Mickley, Guy's Hospital; George Oliver, University College; Richard Douglas Powell, University College; Revett Coleridge Powles, King's College; Frederick William Richards, St. Bartholomew's Hospital; George Henry Savage, Guy's Hospital; Charles Smith, Guy's Hospital; William Vicary Snow, University College; Francis Thomas Taylor, B.A., Guy's Hospital; Henry Trimen, King's College; Ebenezer Fulham Turner, Guy's Hospital.—*Second Division.*—Thomas Robinson Glynn, St. Bartholomew's Hospital; Walter Anstice Harvey, St. Bartholomew's Hospital; Frederick Fawson Lee, St. George's Hospital; Duncan Maclachlan Maclure (st. bef. '39), Westminster Hospital.—EXAMINATION FOR HONOURS.—*Medicine.*—*First Class.*—Revett Coleridge Powles (scholarship and gold medal), King's College; George Oliver* (gold medal), University College; Bryan Holme Allen,* University College; Peter Maury Deas,* University of Edinburgh; Charles Augustus Greaves,* St. Thomas's Hospital, and George Henry Savage,* Guy's Hospital (equal); Alexander Bruce, University College; William Vicary Snow, University College; Richard Douglas Powell, University College; Francis Thomas Tayler, B.A., Guy's Hospital, and Henry Trimen, King's College (equal); Thomas Henry Green, University College; Charles Smith, Guy's Hospital; William George Vawdry Lush, St. Bartholomew's Hospital.—*Second Class.*—Ebenezer Fulham Turner, Guy's Hospital.—*Midwifery.—First Class.*—Revett Coleridge Powles (scholership and gold medal), King's College; Arthur George Mickley* (gold medal), Guy's Hospital; Peter Maury Deas,* University of Edinburgh; George Oliver,* University College, and Francis Thomas Tayler,* B.A., Guy's Hospital (equal); Thomas Bond, King's College; George Henry Savage, Guy's Hospital; Charles Smith, Guy's Hospital; Charles Augustus Greaves, St. Thomas's Hospital, and William George Vawdry Lush, St. Bartholomew's Hospital (equal); Alexander Bruce, University College.—*Second Class.*—Henry Trimen, King's College; William Vicary Snow, University College; Bryan Holme Allen, University College.—*Forensic Medicine.—First Class.*—Peter Maury Deas (gold medal), University of Edinburgh; William George Vawdrey Lush, St. Bartholomew's Hospital; Revett Coleridge Powles, King's College; Alexander Bruce, University College.—*Second Class.*—Bryan Holme Allen, University College; Charles Augustus Greaves, St. Thomas's Hospital.—*Third Class.*—Thomas Bond, King's College.

* Obtained sufficient number of marks to qualify for the scholarships.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, November 23, 1865.—Edward Chaffers, late Confederate States Army; William John Land, St. Mary's Hospital; Theodore Thos. Taylor, Cricklade, North Wilts; John Whitehead, 10 Park place, Liverpool road.—The following gentlemen, also on the same day, passed their First Examination:—Herbert William Fagge, Guy's Hospital; Joseph Loane, London Hospital; Francis Ewbank, St. Bartholomews' Hospital; Thomas Henry Willan, St. Bartholomews' Hospital.

THE COMMISSION ON VENEREAL DISEASE.—Although

the Commission sitting at the Admiralty has now closed the inquiry upon which it has been occupied for several months, and concluded the examination of witnesses, the report cannot be completed for some few weeks. The amount of evidence taken has been considerable. Amongst the principal points established will be the usefulness of the system of examinations instituted under the Contagious Diseases Act, and a wide basis of facts will be afforded for supporting an extension of that measure. There is much evidence to show that the moral usefulness of this restrictive system is not greatly inferior to its physical utility. The women detained, and prohibited from diffusing disease, are brought under religious influences while in hospital, and a proportion of them absolutely reclaimed and restored to their friends. Some doubts have been expressed as to the propriety of enforcing the provisions of that Act, as implying a recognition of the vice which is the parent of disease. But the permanent and frightfully extensive injuries inflicted on the population, and especially on the costly trained men of our naval and military forces, involve facts so serious that they cannot be overlooked, and require restrictive and sanitary measures more urgently than most other diseases of which we seek to limit the spread by legislative measures. Morally and religiously there is reason to believe that the unhappy women are likely to be materially benefitted by the influences brought to bear upon them during periods of detention. The necessity for further Lock hospitals, and the advisability of an extension of the Contagious Diseases Act, will probably be among the most important conclusions deducible from the evidence taken. These are matters of national importance, and it was probably chiefly with a view to the solution of these questions that the authorities appointed this Commission. As to the question of treatment the Commission have found much less diversity of opinion than was alleged prior to its appointment. It is very difficult to find now-a-days anyone who carries out a doctrine of salivation in treating venereal disease : it is almost as difficult to find anyone who is blind to the usefulness of mercury, administered in moderate doses, and employed to combat the progress and effects of the syphilitic poison without any view to salivation. Nevertheless, a few surgeons are found who altogether ignore the use of mercury. The evidence on the other side is overwhelming. The question of the infecting power of hard and soft chancres is likely to be decided on the evidence in favour of both soft and hard chancres possessing a true syphilitic virus capable of infecting the system. A good deal of striking evidence has been adduced in this direction. Although the general result of the Commission will, we apprehend, be to show a substantial agreement of the leading surgeons upon most of the important points in the doctrines and treatment of syphilis, and to confirm the generally received opinions as against the special crotchets of individuals more or less eminent.—'Lancet.'

THE INSURANCE FRAUDS BY A PHYSICIAN.—Thompson Whalley, M.D., of Mirfield, was brought before the Dewsbury magistrates recently, charged with obtaining a security from the British Prudential Assurance Company—to wit, a policy for 33*l.* 6s., on the life of Law Walker, of Mirfield, labourer. The case was similar to the one heard on the previous day, with the exception that the person assured is still alive. In the Medical report, which the prisoner had presented prior to the policy being issued, Walker was described as being healthy, while the fact was that Walker had, for two years, been suffering from abscess of the spine, and had been discharged from the Huddersfield Infirmary as incurable. He had also, within a week or two of the time the policy was effected, been a recipient of relief from the Dewsbury Board of Guardians. Walker swore in court that he knew nothing whatever of the policy upon his life having been effected, and had not signed the declaration produced, but had heard his wife say that she knew something about it. The Bench decided to commit the prisoner for trial at the Leeds spring assizes, and Mr. Allsop, the solicitor for the prosecution, then proposed to go into a charge of fraud upon the British Nation Company to the amount of 1,000*l.*, by a policy on the life of Mrs. Bottomley, of Huddersfield, who is still living; but the Bench declined to go into the case, as they considered the two charges upon which the prisoner had been committed were sufficient. Bail was accepted for the prisoner's appearance, himself in 1,000*l.* and two sureties in 500*l.*—'Manchester Courier.'

FEVER IN SPITALFIELDS.—On Wednesday Mr. Humphreys held an inquest upon the bodies of George Anson and Margaret Anson, his wife, both thirty-eight years of age. Mr. Turner, clerk to the Whitechapel Board of Works, represented that body. The man, George Anson, was a furniture-packer, earning 30s. a week, who rented one room at 2s. 9d. a week at 27 Grey Eagle street, the property of Mr. H. F. Waring, the owner of very extensive house property in Spitalfields and Bethnal-green. Anson frequently complained of the foul state of the house, but without avail. A fortnight ago his wife was seized with illness—sickness, loss of appetite, and a sort of skin over the eyes. He was similarly attacked on two days after, and she died on the 22nd and he on the 24th ult. The actual condition of the house property in question was described as follows by the witnesses examined :—Mary Davis said that she lived on the ground floor, where she kept a coal shop. She had lived there seven years, and during that time had lost six children. Nothing had been done by the landlord to her place during the last seven years, though she paid 4s. a week rent. All her children died under the age of two years and a quarter. She had two living now. In reply to Mr. Turner, she stated that sanitary inspectors had sometimes called, and that they had caused the nuisance from the stable next door to be abated lately. Her sleeping room was below the level of the backyard, and the drainage from the stable in question flowed over her yard and past her window. That was altered. Twenty persons lived in the house. In the back room on the first floor lived a man and his five children, paying 1s. 9d. a week rent, for the room was very small. In the next room the deceased and their son lived. Over that room a woman and her two children lodged, and in the apartment next to hers lived a family consisting of a man, his daughter, and a little boy. They paid 2s. 6d. a week rent. In witness's room the flooring was laid level on the earth ; there were no rafters. Dr. T. Sarvis said that he was called in to the two deceased persons on Saturday week, and found them both delirious in one bed. They had typhoid fever. There was an accumulation of vegetable and other refuse outside the door; the passage and stairs were extremely dirty, the walls dilapidated and filthy ; the closet was in a disgraceful state, and the flooring was partly destroyed. The water, which was kept in an old tar barrel, was quite unfit to drink, through the foul exhalations from the drain and closet. The two persons ill were so surrounded by unhealthy influences, that he considered there was not a chance of their recovery if they remained there. He advised their daughter (a girl of fifteen or sixteen) to have them removed to the Fever Hospital ; that was not done, and they died. Mr. Turner cross-examined Dr. Sarvis with a view to show that it was an actual advantage not to have a dust-bin on the premises, as the rubbish, being thrown into the street, would be removed when the streets were swept three times a week. The witness said that as a matter of fact the same heaps of rubbish were seen by him in the street unremoved from Saturday week until Thursday last. Dr. Henry Letheby also testified to the filthy and insalubrious condition of the place. The inmates informed him that the water could only be used for washing purposes, and there was no tap to the old tar barrels, which they had themselves supplied. Mr. Isaac Battram, assistant-inspector under the Whitechapel Board of Works, said that he had served a notice some time back upon a Mrs. Waring with reference to this house, but it turned out that it was Mr. H. F. Waring, of 450 Hackney road, who was the owner of the property. He was served with a notice on the 24th of October, and with a compulsory notice on Thursday last. There were four house owners named Waring, and they gave much trouble. He had served them with nineteen notices since the 16th of August last. Dr. John

iddle, Medical officer of the Whitechapel district, said hat he had three inspecters under him, and that every ouse in the district was visited and inspected. Grey agle street was the worst place in the district. Fever and iarrhœa prevailed much there. He had to complain of the nduct of Mr. Waring with reference to the state in which e kept his house property. The Coroner having summed), the jury returned a verdict:—"That George Anson id his wife, Margaret Anson, died from typhoid fever; d that the filthy condition and overcrowded state of the emises engendered such fever; and the jurors further y that more prompt measures ought to have been taken th respect to the said premises by the district authoies."

MEDICINE AND SURGERY AMONG THE CHINESE.—At a eting of the West Kent Medico-Chirurgical Society on iday, November 10th, Mr. William Lockhart, F.R.C.S., R.G.S., who has laboured for more than a quarter of a ıtury among the Chinese as a Medical missionary, brought ore the meeting a few details of the results of his obserions. He stated that the Chinese have practically no owledge of anatomy or surgery: they have, however, ne little knowledge of Medicine. They consider diseases der five classes: those proceeding from heat, cold, dry-s, dampness, and wind—being conditions of the atmoıere which induce or vary the various forms of disease. practice, however, these crude notions are, among the ter educated, very much set at nought; and they apply ir remedies to the symptoms, discovering by experience at relieves or cures, and giving the same Medicine when ke set of signs of illness appears. Theoretically, they bad practitioners; but practically they manage simple ases very well; and the results are, on the whole satis-ory as far as ordinary Medical ailments are concerned. ey know nothing of practical human anatomy; and their gery is really barbarous. The little anatomical knowledge y possess is derived from the lower animals, which they ly to the altered conformation of the human body. Still, hey are well educated on many subjects, and have to pass ugh long courses of study, the ordinary class of Medical a are to be considered among the best informed; which ibtlessly enables them to apply principles in keeping h keen observation, and thus become really useful ctitioners of the healing art to all cases except surgery, hich branch of Medicine a lower grade of men is attached. re failures in surgery are very marked and painful. ing no knowledge of the courses of the arteries, they ıot apply a ligature; consequently, many cases of simple nds, where vessels are divided, perish. The same want ıowledge of the bones is fraught with like sad results heir treatment of fractures. All they do with the ure, simple or compound, is to bind it up tightly with id of dextrine consisting of pitch and gum, with plaster 'aris, &c., without having previously adjusted the ure; consequently, one sees limbs distorted in every ble way, and often, too, extremities sacrificed to injuus pressure. Similar plasters are not unfrequently to treat injuries and disease of the trunk, or, in some , purely Medical complaints—hiding, as it were, from vation the indications of illness! Gun-shot wounds, ich Mr Lockhart had seen many, are covered with the compound, and often left unexamined until the most ful consequences ensue—grangrene, &c. Of eye-dis-they have no knowledge.

RDER IN AN ASYLUM.—On Tuesday week a deplorable ly was perpetrated in the West Riding Pauper Lunatic m at Wakefield. One of the inmates named Waite, labouring under an extraordinary delusion, murdered w patient, named Burran, with a garden spade. The an inoffensive and quiet man, was re-admitted for a time into the Asylum in February, 1863, having discharged in 1859, relieved, but not cured of ıtia. He was a woolcomber, and a native of Allerton, Bradford. Waite, who comes from Sheffield, has s been deemed of strong suicidal tendencies, but has been considered dangerous to others. Within the w days, however, he has laboured under great excite-

On Tuesday, about half-past ten in the morning, an attendant left Burran alone making beds in one of the dormitories, while he went to the kitchen for beef-tea for other patients. On returning, Waite, who was then sitting by one of the day-room fires, beckoned to him. The day-rooms are on the same story as the dormitories. Waite said, "If you'll come with me I'll show you something that will astonish you;" and getting up from his seat he led the way into the dormitory in which deceased had been left. On entering the room Kimpton was horrified to find Burran prostrate on his face in the middle of a large pool of blood. Near him was a second extensive patch of gore, and the bedclothes were also covered with a quantity of big red splashes. Lying at a distance was an ordinary garden spade. From this blood was trickling to the floor. Turning aghast to Waite, the attendant asked him what he had done. Waite at first said he had done nothing; but, being pressed, he admitted that he had killed Burran with the shovel. Mr. Cleaton, the Medical superintendent, was at once sent for, and while waiting his arrival the attendant proceeded to search Waite, who was then exhibiting great disquietude and excitement. On him was found a piece of slate about a foot long and three or four inches broad, in the middle of which was a large sanguinary spot. Blood, too, was to be distinctly traced upon the man's clothes. As soon as the search was over Waite fell down in a fit, and was carried out of the room raving. On the arrival of Mr. Cleaton it was found that a terrible onslaught had been made upon Burran. The lower part of his visage was utterly defaced; the facial bones were completely fractured, the structures frightfully lacerated, and the blood vessels at the base of the brain entirely dissevered—in fact, from all appearance, Waite must have made a deadly aim with the edge of the spade at Burran's countenance, and wielded it with dreadful force and effect. Death, from all appearances had ensued instantaneously. On Wednesday evening Mr. Taylor, borough and county coroner, held an examination over Burran's remains. The jury, after a short consultation, returned a verdict of "Wilful Murder" against Jonathan Waite, and he was fully committed upon the coroner's warrant to take his trial at the next assizes.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, DEC. 6.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; St. Thomas's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Obstetrical Society of London, 7 p.m.—Council; 8 p.m. Dr. U. West, "On a "Variety of Placenta;" Dr. Greenhalgh, "On the Merits of Cæsarean Section;" and other papers by Drs. Eastlake, Meadows, &c.

THURSDAY, DEC. 7.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Chemical Society, 8 p.m.—Dr. Gladstone, "On Pyrophosphotreamic Acd;" Harveian Society of London, 8 p.m.—Dr. Sanderson, "On the Relations between the Cattle Plague and Similar Diseases in Man;" King's College Medical Society, 8 p.m.—Clinical Meeting.

FRIDAY, DEC. 8.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, DEC. 9.—*Operations* at St. Thomas's Hospital, 9½ a.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

MONDAY, DEC. 11.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metropolitan Free Hospital, 2 p.m.

TUESDAY, DEC. 12.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.; National Orthopædic Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Outlines of Elementary Botany, for the Use of Students. By Alex. Silver, M.A., C.M., M.D. London: Henry Renshaw.

Journal of Social Science. Edited by Edwin Lankester, M.D., F.R.S., &c. London: Chapman and Hall.

On Cancer: its Allies and Counterfeits. By T. W. Cooke,

Esq., Surgeon to the Cancer Hospital, &c. London: Longmans, Green, and Co.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the Office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

To SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

NOTICE.—*Complaints having reached us of the non-delivery to Subscribers of the copies of the* MEDICAL CIRCULAR, *we have instituted inquiries as to the cause, and have made such arrangements as will prevent the possibility of a repetition of the omission. Any gentleman not having received his copy as usual during the last seven weeks, will be kind enough to intimate the same to the Publisher.*

A READER.—The letter is inserted.

M.D. CANTAB.—The communication has been received.

MR. GRIFFIN'S letter is inserted.

A SUFFERER.—The pretended discovery of spermatozoa in the urine is an old device of the obscene quacks. The so-called spermatozoa shown by these gentry are common paste-eels (*vibriones*) kept for the purpose of deception.

THE HARVEIAN SOCIETY.—The notice has been received.

M.D.—The letter is inserted.

AN ASSISTANT-SURGEON'S Memorial to the Members of the House of Commons has been received.

DR. H.—The newspaper has been received.

MR. H. C.—The nomenclature of skin diseases is a very difficult subject of study, as hardly two authors agree in their views. But you cannot do wrong in consulting the book of Willan and Bateman in the first instance, and then you can read the works of more recent authors.

DR. J. K. (Aberdeen).—It is quite certain that the rinderpest, whatever it may be, is not analogous to the typhoid fever in the human subject, at least if the inflammation and ulceration of Peyer's patches are admitted to be diagnostic of that disease.

CHIRURGUS.—We are very sceptical as to the existence of an antidote to poisoning by prussic acid, which is too rapid in its operation to admit of any antidote being successfully administered.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 78 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases. Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d each. Photographic Lenses. Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second-hand Surgical Instruments forwarded for 6 stamps.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

Hospital for Diseases of the Skin, Blackfriars.—To Surgeons.—The Sub-Committe for the appointment of Medical Officers to this Hospital require the addition of one Surgeon and one Assistant-Surgeon to their present staff.

Candidates for these appointments must be Fellows of the Royal College of Surgeons of England, not practising Pharmacy, and must adduce evidence of having given attention to the study and treatment of Cutaneous diseases.

Applications and Testimonials must be sent under cover to the Secretary on or before December 11th, endorsed, "Medical Officers' Application."

By Order of the Sub-Committee.
ALFRED S. RICHARDS,
Secretary.

Christmas Accounts.—Merritt and HATCHER will send, post free, on receipt of four stamps, a variety of Samples and Prices of MEDICAL BILL FORMS, by which a great saving of time in making out accounts is effected.

Merritt and Hatcher, Printers, Engravers, and Lithographers, 2 Grocers' Hall Court, Poultry, London, E.C.

Geo. Smith and Co.'s Pure Extract of CALVES' FEET for INVALIDS and CULINARY USE. Sold in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Druggists, Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland street, Regent street Office: 94 Upper Thames street, E.C.

Pepsine and Pepsine Wine.—Boul- DAULT begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Chemist in Ordinary to the Queen and H.R.H. the Prince of Wales, 227 Oxford street, London, to whom all applications respecting it must be addressed.

Third Edition, with Further Remarks by Dr. CORVISART, Physician to the Emperor of the French, edited by W. S. SQUIRE, Ph. D.; published by J. Churchill, London; may be also had of the Author, 277 Oxford street, price Sixpence.

T. & H. Smith's Codeia Lozenges These Lozenges have a remarkable effect in allaying COUGH, and IRRITATION of the THROAT and CHEST.

Prepared only by T. and H. SMITH and Co., 21, Duke Street, Edinburgh; and 69, Coleman Street, London; in Boxes at 1s. 1½d. and 2s. 9d. each.

Medical Fixtures and Glass Manu- FACTORY, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Altering in the above Profession, that he has an extensive assortment of SHOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc

Brass and Zinc Door-Plates, —C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges Chemists' Shops fitted up with Window-sill Plates in the plain or C.G. Patterns. Lists of Prices post free.

Plates altered and repaired.—Country orders punctually attended to.
36 CHANDOS STREET, CHARING CROSS, W.C.

LADIES' SURGICAL BELTS,

Abdominal Supporters, Elastic Stockings and Bandages, Rupture Trusses, Chest Expanders, Spinal Corsets, Instruments for Piles, Prolapsus Ani and Uteri, and every description of Mechanical Appliances, with all the latest improvements, are manufactured at reduced prices by

Mr. CHANDLER, 66, BERNERS ST., OXFORD ST., W.

A lady of great experience attends. Illustrated Catalogues forwarded. A liberal discount to the Profession.

H. Silverlock's Medical Label Ware- house, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctor's Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.
YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.
SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.
LABEL CASES for the use of Surgeons, 14s., 18s., and 24s.
LATIN SLIP LABELS for Wholesale Druggists.
Catalogues sent on application.

Treloar's Kamptulicon COCOA-NUT MATTING,
AND OTHER DURABLE FLOOR COVERINGS,
67 LUDGATE HILL, LONDON,
Three doors from the Railway Bridge.

The Medical Circular.

REVIEW OF BOOKS.

he Principles and Practice of Medical Jurisprudence. By Alfred Swaine Taylor, M.D., F.R.S., Professor of Medical Jurisprudence and Chemistry in Guy's Hospital. Pp. 1186. London: Churchill and Sons. 1865.

edical books in the present day seem to undergo a kind alternate process of expansion and contraction, or *vice rsâ*. A small volume makes its appearance in the first stance, perhaps, professing to set forth in a condensed m the facts and theories embraced in a given department Medical knowledge; but this gradually swells, by the hesion of new material, to a bulky tome, or the addi- nal matter is compressed, by means of using smaller pe, into a book of the same outward size as its prede- ssors. In other cases the type and the pages and the mber of the volumes are all augmented, until the whole umes an awful degree of magnitude, inspiring a kind of ror into the mind of the student who has to cram for examination, and perhaps awakening a somewhat nilar feeling in the examiner himself. Anon it is found at there is a redundancy of material in the ponderous ok of elements, and forthwith a ruthless editor cuts wn, with unsparing hand, an enormous amount of la- riously collected details, and the mountain again shrinks o the dimensions of a hillock.

Dr. Alfred Taylor's 'Manual of Medical Jurisprudence' first peared in the modest form which we have just alluded to one of the early phases in the history of a modern work Medical knowledge, but as it has been for twenty years fore the Profession, and passed through seven large tions, the accretion of matter which has attended each cessive edition has rendered it necessary to revise the an on which it was originally constructed, and to amplify e whole subject so much as to fill the large volume now fore us. It is only right to mention, in reference to the servations above made as to the expansion and contrac- n of books, that Dr. Taylor has not left to others the k of condensing his pages, but that he continues to do himself, and he announces that the small volume will be ublished as hitherto, to serve as a manual for the use of dents of Law and Medicine. Thus the reader with ited time will be able to gather the outlines of the de- tment of Medical Jurisprudence from the careful usal of the manual, while the more advanced scholar or titioner will find in the larger 'Principles and Practice' full discussion of all the topics on which opinions are en, together with numerous reports and analyses of law es illustrating the views propounded in the text.

he 'Manual of Medical Jurisprudence' is so well wn, and so generally used as a text-book, that it would uperfluous in us to offer any testimony as to its merits, we rather confine ourselves to the duty of pointing out features in which the present large volume differs from small one. Among the new subjects introduced are the s and Phenomena of Death, with an account of the nges which take place in the Dead Body, a subject ch has been lately very ably illustrated by a series of ndred cases in Guy's Hospital, collected by Dr. Taylor self, and Dr. Wilks; Putrefaction in Air and Water its Conditions; the Identity of Bones, Skeletons, and ilated Remains; Sudden Death, which subject, how- , is not very fully treated, except as regards death from on or violence; the Presumption of Survivorship; ntaneous Combustion, which is very amply discussed, only with reference to its alleged occurrence in the an subject, but as it occurs in certain vegetable and ral substances; and Life Insurance, which forms the ct of the last chapter.

In those chapters which admit of illustration, engravings have been introduced, the subject of Poisoning being rendered the more intelligible by the representation of crystalline forms of mineral and organic poisons as observed with the microscope; and the leaves and seeds of poisonous plants are also represented, the leaves being engraved from photographic copies of the natural leaves, showing their complete form and structure, and the seeds of their natural size and shape as well as magnified. These engravings are exceedingly well executed, the crystalline forms are very distinctly delineated, and the botanical illustrations (white figures on a black ground), are life-like in their accuracy.

The progress of Medical Jurisprudence, or in other words the multiplication of cases in which a Medical man is liable to be consulted and examined in courts of law, has been so great in late years that the most laborious industry, as well as the most refined science, is necessary to keep pace with the questions daily raised in this department. The difficulty is infinitely increased by the inherent complexity of some of the questions discussed, by the advances made in chemical and microscopical science, and, in another direction, by the conflicting decisions of judges, the hair-splitting tendencies of barristers, and the general ignorance, on all scientific points, of juries. Thus, a book on Medical Jurisprudence is necessarily loaded with the records of cases and decisions, and the author sometimes agrees with, and sometimes dissents from, the conclusions adopted. Dr. Alfred Taylor has been in the habit, for a series of years, of watching cases in which Medical men are engaged in the law courts, and he himself has had no small personal experience of the difficulties in which even a highly skilled and scientific witness is often involved. In the present large work we accordingly find the details of a great variety of cases, indeed, we might say of all the cases involving Medical questions tried of late years, and we must admit that, even in those in which he has himself been personally engaged, and in some of which his side has been unsuccessful, his observations are generally fair and impartial. The worst part of our present system of Medical Jurisprudence is that Medical witnesses are called for one or other side of a legal case, and thus almost necessarily become partisans, instead of being unbiassed advisers of those who administer justice; but this subject, however important, is foreign to our present review, which we close with the observation that Dr. Taylor's 'Principles and Practice of Medical Jurisprudence' is a work in every way worthy of the previous high reputation of the author.

Manual of Materia Medica and Therapeutics; being an Abridgment of the late Dr. Pereira's Elements of Materia Medica, arranged in Conformity with the British Pharmacopœia, and adapted to the Use of Medical Practitioners, Chemists and Druggists, Medical and Pharmaceutical Students, &c. By Frederick John Farre, M.D. Cantab., F.L.S., Senior Physician to St. Bartholomew's Hospital, and Lecturer on Materia Medica in St. Bartholomew's College. Assisted by Robert Bentley, M.R.C.S., F.L.S., Professor of Botany in King's College, London; and by Robert Warington, F.R.S., F.C.S., Chemical Operator to the Society of Apothecaries. Pp. 614. London: Longman, Green, and Co. 1865.

There are scarcely any practitioners of middle age who have not heard of, even if they have not read, that vast storehouse of pharmacological knowledge known as 'Pereira's Elements of Materia Medica.' Originating in a course of lectures delivered by that physician, and published in the columns of the now extinct 'Medical Gazette,' they made their appearance in an expanded form, in a book of two volumes, which subsequently swelled still more amply into three. In this massive treatise or encyclopædia was contained everything relating to Materia Medica in its widest sense, and the author appeared to have made it his business to collect together not only all the information he could find as to the drugs employed in Medicine, but also as to every other therapeutical appliance, and he moreover amply discussed the different modes of classification of

drugs, and the different opinions held as to the efficacy of each one, and the methods of its administration. The consequence was that the work outgrew the capacities of the readers for whom it was intended, and Pereira's 'Materia Medica,' while it formed a valuable repository of facts for teachers and lecturers, became, from its very bulk, and the multifarious nature of its contents, almost useless to the busy practitioner and the student.

The task of condensation, which had therefore become necessary, in order to meet the demands of the present generation of readers, has been entrusted to the able and experienced hands of Dr. Frederick Farre, who, in conjunction with Mr. Bentley, in the botanical department, and Mr. Warington, in the chemical, has reduced the book to something like readable proportions; and, while cutting away much matter, which, however valuable, did not perhaps precisely belong to a work on pharmacology, he has left all the essential parts of the subject untouched, except where the progress of science has rendered it necessary to correct errors or to add new facts. Dr. Farre tells us in his preface that his plan of excision has been formed upon a strict adherence to certain rules—namely, to omit all remedial agents, except those which Dr. Pereira termed pharmacological, thus passing over the influence of the mind, of light, heat, electricity, food, exercise, climate, &c. Secondly, to omit all pharmacological remedies which are not officinal, or contained in the British Pharmacopœia, and thirdly, to omit all classifications of medicines, except the two which Dr. Pereira himself adopted—namely, one founded on the chemical classification of the inorganic bodies, and on the botanical and zoological classification of the plants and animals yielding the organic bodies, the other classification founded on their physiological effects.

A very remarkable difference between the present volume and Pereira's 'Elements' is of course observable in the fact, that the drugs in the former are all arranged in accordance with the British Pharmacopœia, while in the latter the formulæ of the different colleges of London, Edinburgh, and Dublin, were all described under each drug. The rigid exclusion, too, from Dr. Farre's work, of all articles not included in the British Pharmacopœia, deprives the reader of the description of a few valuable drugs, while it includes the description of many which may perhaps be considered useless or objectionable; but these were essential features of the condensed book, and we have no right to find fault with Dr. Farre, because he has carried out his own intentions. The British Pharmacopœia was avowedly a compromise of conflicting claims, and the next edition, whenever it appears, is not likely to please everybody: some drugs will inevitably be introduced, the value of which is not universally, or even generally recognised, while still many more will be omitted in spite of the strong recommendations of those who are in the habit of using them. On the whole, we cannot say that in our opinion the British Pharmacopœia is an inadequate representative of the existing state of pharmacology, although it must, like other similar works, be subject to periodical changes, in accordance with the advance of discovery in science and art.

In the therapeutical portions of Dr. Pereira's book, the present editor has had rather a difficult task to perform, because some of the opinions expressed in the original are not in accordance with those held in the present day, when, we may remark parenthetically, it is the fashion to depreciate therapeutics altogether. Thus, Dr. Pereira's views upon blood-letting, and the use of mercury, for instance, would now probably be warmly contested, but Dr. Farre has thought it better not to interfere with Dr. Pereira's opinions, except in cases where they are manifestly erroneous, as he justly remarks that the present opinions and practice are still recent, and may in their turn yield to further experience.

That it was desirable to retain the substance of Pereira's 'Materia Medica' for the use of the present race of students and Practitioners of Medicine and Pharmacy, cannot be doubted, and we have no hesitation in expressing our opinion, that the work in its present form will be, as it deserves to be, universally acceptable.

Hand-book for Yellow Fever: describing its Pathology and Treatment, as observed in unintermitted Practice during Half-a-Century; to which is adjoined a Brief History of Pestilential Cholera, and a Method of Cure, as detailed in a Series of Official Reports made during the Prevalence of the Epidemic in the Island of Trinidad in 1854. By Thomas Anderson, M.D., Health Officer in Trinidad. Pp. 80. London: Churchill and Sons. 1866.

When a gentleman offers us the result of the experience of nearly half-a-century, we are bound to receive it at least with respect, and with this feeling we opened the little volume before us, which gives a brief account of the yellow fever, and a still briefer account of cholera. As Dr. Anderson has attended many cases of yellow fever, he is enabled to write practically on the treatment, and that which he recommends is the administration of an infusion of ipecacuanha in the early stage, followed by a full dose (ten grains) of calomel, and some castor-oil, and as soon as the bowels are unloaded, a mixture is to be given containing quinine, held in solution by sulphuric acid. This mixture is to be taken in divided doses, until a quantity amounting to thirty grains of quinine has been administered, after which period the quinine may be resumed, but at prolonged intervals. The treatment of cholera, as proposed by Dr. Anderson, consists in the administration of ammonia in the form of a fluid drachm of the aromatic spirit, with a claret glassful of Seltzer water, and repeated hourly till the frequency of the discharges is checked. This result is said by the author to ensue in a few hours if given early, but he gives no details of cases so treated. Dr. Anderson, in his preface, anticipates little commendation for his book on the part of the Profession, and in this respect, he will, perhaps not be disappointed, but he hopes that the community at large will be more indulgent, which may perhaps be the case. This "Hand-book," in truth, has very little Medical value.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. W. H. DICKINSON, of St. George's Hospital, commences the number with an address "On the Progress of Medicine during the last Three Centuries," being the Thruston speech, delivered at Caius College, Cambridge, 1865. In this brief, but discursive sketch, Dr. *Dickinson* passes rapidly in review the condition of Medicine and its professors from the time of Galen to that of Caius, and from the latter to that of the physicians of our own day. The state of Medicine in Europe at the time of Caius is thus described:—

"The time of Dr. Caius was a period of change and activity. The influence of the priesthood was declining before the spread of knowledge. The dominant class had been enabled to hinder, but not to prevent, the rise of a spirit of inquiry. Dr. Caius was seven years old when Luther nailed his ninety-five propositions to the church-gate of Wittenburg. The age of authority was ending and the age of inquiry was at hand. Galen did not fare better than the Pope. Vesalius was labouring at anatomy, and after spending a life in turbulent controversy, had so far corrected and added to the descriptions of the older writers that the science could scarcely be carried further with the aid of the microscope. All the anatomical discoveries since his time have been minute, such as pertained to the lymphatics, the valves of the veins, and the distribution of nerves. Surgery, which depends on the large facts of anatomy and on the obvious effects of outward applications, was consequently further advanced than the more profound and indirect science of Medicine. The old belief that all nature consisted of four elements—earth, air, fire and water, had been expanded into a complete system of Medicine, of which traces may be found in the present day. There were four humours present in the human body—blood, which had the properties of air; melancholy, those

of earth; choler, of fire; phlegm, of water. These were the 'second elements,' or the 'elements of man.' The functions of the organs were arranged accordingly. The liver made the blood; the spleen, melancholy; the gall-bladder was the source of choler; the stomach, of phlegm. As one or another humour prevailed, the temperament of the individual was formed, and he became sanguine, melancholy, choleric, or phlegmatic. His character and morbid tendencies depended upon the predominance of one fluid over the others. The old physicians gave elaborate rules by which the temperament can be ascertained. The appearance of the person, the colour of the skin and of the urine, the boldness or timidity of the temper, the colour of objects presented to the imagination in dreams, the sex of progeny, and many other particulars, are dwelt upon as signs of one of the four constitutions. Nor was this an unimportant question; not only were food and medicine given with regard to these considerations, but young men were admonished that their success in life depended upon their bearing them in mind in choosing a profession."

——Inspector-General Sir RANALD MARTIN continues his observations "On Hepatic Disease amongst Europeans in the East Indies," his present subject being "Chronic Engorgement of the Liver." In the treatment of this complaint he long ago became convinced of the inutility of mercury, and he therefore employed the nitro-muriatic acid in the form of bath, the use of which he describes at some length, and the efficacy of which he illustrates by the detail of several cases.——Mr. ROBERT ELLIS contributes a paper "On the Radical Cure of Prolapsus Uteri," and describes the operation he performs for the remedy of that condition. He states that all cases are not suited to the operation, but that a judicious selection should be made in order to insure success. Patients above sixty-five and young unmarried women are not fit subjects, but married women at the close of the child-bearing period up to fifty-five or sixty, offer the most favourable conditions for the proceeding. The operation consists in denuding a portion of the mucous membrane of the vagina, and then joining together the denuded surfaces by *flat ribbons* of silver, a method of suture introduced by the author of the paper.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. C. HANDFIELD JONES continues his Lumleian Lectures "On Some Points in the Pathology of Nervous Diseases," and he now describes the condition which he terms "inhibitory paresis" of the heart, or a kind of semi-paralysis of that organ, caused by nervous influences, and not by appreciable disease. Dr. Jones adduces several cases illustrating the existence of this condition as a consequence of nervous agency; but, as the whole subject is a difficult one, it will be better to describe its principal features in Dr. Jones's own language:—

> If, now, we consider the various causes which we have seen to produce inhibitory paresis, we shall, I think, be satisfied that they are all such as are likely to exercise an injurious and depressing influence on the nervous centres. Thus strong currents of electricity, cold and wet, intestinal irritations, fæcal accumulation, gastric, cutaneous, uterine irritation, diseased teeth, and the like, can scarcely be regarded as promoters of the natural and healthful functional excitement, but very much the reverse. The special effect which they produce depends in great measure on which part is the weakest, and, consequently, most prone to suffer depression or derangement of its normal mode of nutrition. The inhibitory influence seems to be more ready to act on the nervous centres which it first reaches, but it may also, as we have seen, diffuse itself very widely, or may only act on a remote centre. It probably produces its injurious effect wherever the resisting power is insufficient; in fact, *it finds out the weak point.* Diseased teeth commonly produce palsy of some of the highest situated nerves; but in a case recorded by Mr. Castle, of New York, they produced paraplegia, which soon ceased after their removal. The essential idea of the inhibitory theory is that an impression conveyed to a nervous centre by afferent nerves may weaken or paralyse, instead of exciting, its action, either from the congenital or acquired debility and sensitiveness of the centre itself, or because the impression is unduly intense or absolutely injurious. Both these things have, in every such case, to be considered—viz., the state of the nerve force, and the kind and amount of impression, as the resulting phenomena will vary with the variations of either. A gentleman of high scientific attainments told me the other day that the music (?) of a street organ distressed him so as to render him almost pulseless. Here, of course, the nerve force was in a very feeble and impressionable condition. It is clear that these views are of very material importance in relation to practical medicine, that they are utterly opposed to anything like routine procedure, and that they lead us to careful consideration of each individual case, not only as regards physical signs, but also as regards the very varying functional energies. It may be added that the state of the nervous centres seems also to determine to a great extent the length of time during which the depression shall continue, even after the inhibitory agency has ceased. Stronger centres recover at once, as soon as the morbid impression is removed; weaker ones, more slowly, and sometimes not without the aid of tonics and restoratives. Indeed, we find the same variations to prevail here as we do in many diseases. Two persons are affected with the same malady at the same time—it may be rheumatic fever; in one the system soon throws off, as it were, the disorder, and springs back to health; in the other it abides in its ill state, and shows but little tendency to spontaneous recovery. This must, I think, ever greatly interfere with attempts to ascertain what is called the natural history of disease."

——Dr. GEORGE HARLEY continues his lectures "On the Diseases of the Urinary Organs," his present subject being the pathology of albuminuria. He describes the microscopical appearances of the blood-corpuscles and the hyaline casts found in the albuminous urine; and in reference to the former he remarks that they sometimes appear nucleated and irregular in outline, but he observes that these appearances are partly optical phenomena and due to the action of saline urine on normal blood-cells. He then successively describes the hypertrophied kidney, the fatty degeneration of the kidney, and the waxy and the cirrhosed kidney.——Professor UNTERBERGER, of Dorpat, Russia, Director of the Veterinary School in that city, contributes an article "On the Cattle Plague," and confirms the opinion now entertained that the disease came to England from abroad, but he denies that it came from Revel. In the treatment, Professor Unterberger recommends neither medicines nor inoculation, but approves of the adoption of strict measures of veterinary police for the eradication of the pestilence.——Mr. WM. WATMOUGH relates a "Case showing an Unusual Course and Termination of an Abdominal Tumour." The tumour opened externally, and discharged a large quantity of what appeared to be gall stones. They consisted of cholesterine with nuclei of carbonate of lime and biliary pigment.

'JOURNAL OF SOCIAL SCIENCE,' including the Sessional Papers of the National Association for the Promotion of Social Science. Edited by EDWIN LANKESTER, M.D, F.R.S. &c. No. I. NOVEMBER, 1865.

This Journal has been started with the object of circulating

the papers read before the meetings of the National Association for the Promotion of Social Science, and of supplying original papers and various information on the subjects embraced in the departments of the Association. These departments, we are informed in an introductory address, are classed under the heads of Law, Education, Political Economy, and Health, which topics, it is contended, should be studied not alone from a professional point of view by certain classes of persons, but by the community at large. The manner in which it is proposed to treat these subjects may be gathered from the following extract from the introduction :—

"What we shall endeavour to show is, that there is no member of a civilised community, however low, that is not interested in understanding and discussing the great principles by which the welfare of society is regulated, and it will be our constant aim to present the subjects with which we deal in a language and style that can be appreciated by the great bulk of those who have been educated to read their own tongues. Whilst we hope to secure contributors to our pages whose names will at once be a guarantee of the soundness of their views, and the earnestness of their purpose, our pages will be open to the freest discussion. At the same time that we can admire the earnestness with which men maintain their religious and political principles, we shall not advocate practical action in social questions on the grounds of religious and political parties. Holding the right of every member of a free state to act upon his political and religious views, we shall be open to the fair and honourable discussion of all questions connected with the recognised sphere of the activity of the Social Science Association. That the questions interesting to human society must have a limit in our pages, as well as in the proceedings of the Association, will be evident to all when it is considered that, in its widest sense, social science embraces the consideration of the principles involved in the cultivation of the fine arts, the science of theology, and the practice of law and medicine."

Besides the proceedings of the Association for the Promotion of Social Science lately held at Sheffield, which are very fully reported, the present number contains articles on the Cholera, the Cattle Plague, the Protective Duties of America, and the Examination of Girls, and there is a monthly chronicle on passing events, together with a report of the proceedings of societies, and a department for reviews and one for correspondence.

"CYCLOPS'" THIRTY-FIRST LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—I have shown in my previous letters that large quantities of aqueous fluids are made in the body independent of the blood, and that these stand in close relationship to the fat. That while on the one hand fat is made by the inspissation of inorganic fluids formed from certain gases, and that it has of itself when so formed, the power of holding a large quantity of fluid as a reservoir in many parts, for the common uses of the system. In none probably is it so important as in its connection with the glands; organs which have large powers of secreting important salts to be used again in the system and which are deeply imbedded in fat. It is my duty to show that it would be perfectly impossible for the salivary and other glands to form their peculiar secretions without the inorganic fluids supplied by the fat, and furthermore that it would be equally impossible they could be conveyed from their secreting cells without being diluted with inorganic fluid elements. It seems to be so deeply a rooted conviction that all elements are made from the blood that I cannot reiterate my denial of this too frequently. Nature having placed certain organs and structures of a certain character in given localities, has consequently endowed them with their own peculiar powers. Nothing can be more remarkable in a physiological point of view than that periosteum secretes bone. Plant the periosteum where you may, the result will be ossific deposit. If bone is destroyed and becomes exfoliated, a fresh periosteum must be first formed before that portion of bone is renewed. The blood, therefore, supplies only structural power to periosteum and periosteum supplies bone. Similar facts occur throughout all other structures. Blood supplies glandular structure, but the glands from their own inherent powers secrete certain elements. If we take the salivary glands alone and consider the immense amount of saliva that is formed daily by every individual, the wonder is, not how the glands can do it, but how the blood can supply sufficient elements as well as the inorganic aqueous matters; and so it will remain to the end of time unless the question is solved in a more simple manner. In all analyses of these secretions a vast percentage is always found to be water, which holds in solution their constituent bases. The salivary glands themselves evidently form these latter; but it is totally impossible they can also form the aqueous or diluent mass as well. Therefore, this is supplied by the inorganic fluid derived from the fat, which in the first place helps them in the formation of their bases, and adds the principal quantity of fluid when these are excreted from the glands themselves. There does not appear to me a wiser or more beautiful provision of Nature, than in the gland theory viewed in this way. It opens up a large field of thought and at once relieves us from the oppressive idea, as well as the impossible one, that the blood is the only active medium in all these matters.

Let us see how modern physiologists view these things. They say that the secreting glands of plants are presumed to be structures specially adapted for the elaboration of secretions, but yet they profess not to understand them. They infer that a peculiar condensation of tissue secretes a fluid and then excretes it in as peculiar a way, and suppose this process to be connected with the vascular system in the interior of the plant. In fact, all being doubt and uncertainty, specious theories are made, but always with the plea that this or that fact has not been sufficiently investigated, or not sufficiently revealed, and, therefore, not yet understood.

Speaking of the acid and alkaline secretions supplied by plants, "We know," say the best authorities, "scarcely anything." Still they are always harping on the same string—namely, that all secretions, glandular of course included, must be eliminated from the blood. But if anyone once begins to investigate all these matters with a doubt how it is possible these things can be done, it is then that the more he reads up the subject even by the best authorities, the less satisfaction he will get, and his doubts will at last culminate in perfect disbelief, and he will arrive at the same conclusion I have long since, of the speciousness of the theories advanced.

Now, one fact of this kind is as good as a thousand, and I will take it from the latest, as well as what is considered the first authority. In speaking of fat I have alluded to its investing membrane, which is an organised substance whose duty is to envelope a large inorganised mass and for no other purpose whatever. Of the same character are the fasciæ of glands. Speaking then of the glands, our authorities say :—"In all cases, the secretion is formed by a special organ or gland, more or less complicated in structure; it may be regarded as a sac, formed of a membrane, on the outside of which blood-vessels ramify and provided with an orifice by which the contents may be either transmitted to the place where their presence is required or carried out of the system altogether." "*It is the membrane of which this sac is formed that constitutes the true secreting organ*; and, although our means of observation do not at present enable us to distinguish any marked differences in its structure in the different glands, it is *manifest* that such variations must exist, since the conformation of the secreting sacs, or tubes, into masses of various shape and texture, has nothing to do with the character of their products, this

being entirely determined by that of the membrane through which they are transuded from the blood." "It is not a little curious to remark, also, that all the secreting membranes of which glands are formed, are prolongations either of the skin, or of the mucous membranes, which are continuations of it." "A secretion of a more peculiar nature is formed by one of the modifications of cellular tissue, *the adipose*, the fatty matter which its vesicles contain being strictly a secretion *from the membrane forming their walls*, and as these cells have no outlet, their contents are stored up in them, like the corresponding secretions of plants, until their re-absorption is required for the purposes of the economy." So, in the first place, the "*secretion is formed by a special gland, with an orifice to transmit it where it is required, or to carry it out of the system altogether.*" But if it is required by the system, it goes to the right place, and if it is not, it somehow vanishes. This is very pretty logic, as Nature ever made anything that she did not want, and always for some specific use. But then the sac or investing membrane of these glands is considered in the next paragraph "the true secreting organ." Now, this is quite of a piece with the other. Then I say, why this work of supererogation at all? The sequitur is quite natural, the confession of not knowing how all these things happen, though it is naively said that it is *manifest* something does happen. Then to say—"the various shapes and texture of the sacs and tubes have nothing to do with the character of their products" is equally gratuitous, for did they not, Nature could not have made them so. But that, "all the different products are entirely determined by the investing membrane through which they transude from the blood." Yet, this is actually written and firmly believed in, with all the list which I have quoted above. No wonder Medicine is a mystery, and its practice oftener a curse than a blessing to mankind, when the physiology of its simplest secretions are not understood, and the *half-science* itself in so low a condition. Let us trace a number of causes to prove one great fact. A thin girl marries—conception takes place with gradual utero-gestation. The first thing noticed, is a general dampness occurring throughout the body. In fact, the whole character of the individual becomes altered. The neighbouring organ to the uterus, namely, the colon, increases in calibre, more hydrogen is generated and oxygen proportionally consumed, and more aqueous elements are the result, so much so, that in a few months a greater deposit of fat ensues from the causes I have laid down. Every gland becomes more active and is able to secrete more of its ases of supply, and the surrounding fat supplies also more aqueous diluents. The sympathies throughout the whole system are roused to their utmost, and for the first time, the breasts assume a character they never had before. They enlarge, and after parturition secrete milk in often very abundant quantities. Now, here are glands different in their character to the salivary. It is a fact noticed by the older physiologists that the milk glands, or rather the membranous fasciæ that invests them have very few blood-vessels compared to their bulk, and even with the great increase of the mammary glands during lactation, the arteries preserve their almost capillary minuteness throughout all their ramifications. Now, this fact is totally at variance with the notions above stated. If there was any truth in them, the blood-vessels in the investing membranes ought, as a matter of course, to become larger and carry more blood to the parts; which they do not. But as respects the glands themselves they become larger and more active, and the quantity of fat itself surrounding them is greatly increased. Still the older physiologists worked hard for their theories, by saying that the milk was excreted from the chyle; but this reversion of the lymphatic vessels being justly considered untenable they, like all others, fell back upon the blood. It will thus be seen that men wish "to reckon without their host," how they run into no end of errors only to be equalled by their infidelity in doing so. The host in all these cases being the whole of the body, have been left out altogether. Nothing appears clearer than that the solids, fluids, and gases form the most perfect equilateral triangle, and if once this third be admitted into all the laws of the secretions of the body, mountains of vexed questions would soon subside from the field of physiology. Milk may be considered as one of the most compound of animal fluids whose parts have but an imperfect affinity to each other. It contains but a small quantity of azote, with a predominance of hydrogen, oxygen, and carbon; but it also contains several salts such as muriate of soda and potass and phosphate of lime. Now muriate of potass does not exist in the blood, and this led some of the older physiologists to doubt the blood supplying the mammary glands at all, with the materials whence milk is secreted. And this is the most consistent view of the whole matter, for there is no doubt in my own mind that the organic constituents of the body have been too much considered and supposed to do more than it is possible they could do, to the exclusion of the inorganic elements and the gases, which has been the fashion entirely to ignore. The consequence has been that most untenable doctrines have been promulgated, which have only served scholastic metaphysicians to lecture upon even in the present day, to the wonder of their hearers only, for while they have endeavoured to retain all these matters in their minds, they have felt they could not do so, for the simple reason that they contained no truth for the mind to grasp.

In last week's MEDICAL CIRCULAR, a distinguished chemical physician, lecturing on fat, says, "that the process of fattening is caused either by taking more fatty matters into the system than can be removed by the influence of oxygen or by diminishing the quantity of oxygen supplied to the tissues." There is truth at the bottom of this, but it is not made apparent by scientific deduction. He must first teach that nothing can be taken into the system that does not undergo the necessary changes to their primitive elements and then become recombined or organised anew. Let him teach that the hydrogens are generated to a large amount in the system from the fat taken, and consequently absorb the oxygen freely. The natural results being aqueous elements, which become inspissated, and fatty deposits are the result. When there is a diminished supply of oxygen to the tissues with a full supply of hydrogen, then greater quantities of fat necessarily ensue. But let him give up the false idea that either eating fat itself or fat producing elements supply fat *per se*, for they do no such thing. This can only be done in the way I have previously said, by their conversion into hydrogens and then combining with oxygen, and if this is not done, many persons to my own knowledge who are great consumers of fat, never made fat nor carried fat themselves in any like proportion.

The further uses of this valuable inorganic mass in its relation to the glands in the formation of diluents to assist the bases of their secretions in the economy of the system. I will further illustrate in my next letter.

I am &c., CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

THE CATTLE PLAGUE.

The Edinburgh Committee on the Cattle Plague, having been commissioned by the Royal Cattle Plague Commission to make observations and experiments in reference to the prevention and treatment of the cattle plague, have considered it desirable, in addition to the experiments on treatment which they propose to institute themselves to obtain a record of observations and experiments made by as large a number as possible of qualified veterinary practitioners throughout the country. With this view they have drawn out the following suggestions for methods of treatment of various kinds, prophylactic and curative, which they are anxious should be tested on an extensive scale. They have also drawn up a schedule for the purpose of rendering definite the record of the results of the methods of treatment suggested by them. The committee, before specifying the various methods of treatment in detail, would premise a few general remarks which they consider to be applicable to all cases:—1. As to general sanitary measures, disinfection, &c.—The committee content themselves with referring

for full information on these matters to the supplement of the report of the Royal Cattle Plague Commission, which is in the hands of all veterinary inspectors. 2. As to food.—The committee deem it desirable to state it as their opinion that as a general rule, at all stages of the disease, and whatever treatment is used, food should not be pressed on the affected animal. They believe that too much even of the softest food is hurtful, the powers of digestion being so greatly impaired by the disease. During the earlier stages, they believe that the safest articles of diet are oatmeal gruel, barleymeal gruel, with linseed tea, hay tea, or bran tea, and that little if any addition to these is needed. During convalescence, it is also very necessary that the food should be both sparing and of easy digestion. The same diet as during the earlier stages may be continued, with the addition of mashes of well-boiled turnips or carrots, but in moderate quantity. When rumination commences to be re-established a handful of sound hay, damped with salt and water, may then be given in addition. 3. As to the maintenance of the heat of the animal.—The tendency to chill of the surface is a marked feature of the disease, and it is very essential that the animal should be guarded against cold. The byre should be kept heated up to a temperature of 65 deg. The animal should be thoroughly rubbed down from time to time, and be kept covered with an ample clean rug fastened on with a roller or band of any kind. 4. As to the state of the bowels.—In the early stages they are apt to be constipated. To remove this condition, mild laxatives may be required, but strong purgatives of all kinds are both unnecessary and unsafe. The best laxatives are either raw linseed oil, in the dose of a chopin-bottleful (an English quart), or from 2oz. to 3oz. of flowers of sulphur, mixed up with two pounds by weight of treacle and two chopin-bottlefuls of water. These doses may be repeated cautiously according to circumstances. Sometimes, even in the early stages, but more frequently when the disease has continued for some days, diarrhœa or scouring is apt to come on, and to prove irritating and exhausting to the animal. The simplest and best treatment for this symptom is one ounce of laudanum, mixed with a chopin-bottleful of lime-water, repeated twice or even thrice a day, if necessary. Having thus premised these general recommendations, the committee proceed to state in detail particular methods of treatment, classified under the heads of—A. Diaphoretic and stimulant treatment; B. Acid treatment; C. Restorative treatment without drugs; D. Prophylactic treatment. A. Diaphoretic and stimulant.—The committee are anxious to give a full trial to the method of exciting sweating by the means of vapour bath. The method of using this agent is as follows:—The animal is to be placed in a stall enclosed on all sides, the height of the enclosure being a few inches more than that of the animal. Over the top of the box or enclosure thus formed is thrown a tarpaulin, which should cover it completely, with the exception that an opening is left in it sufficient for the animal's head to pass through. There is then to be placed on the floor of the enclosure, under the animal a tub containing boiling water to the depth of half-a-foot. A continuous evolution of steam is to be maintained for half-an-hour by means of red-hot bricks thrown into the tub one after another. Under the use of this steam bath, if properly managed, the animal may be expected to become warm and to perspire profusely. After each vapour bath the animal should be washed with tepid water containing M'Dougall's disinfecting soap, taking care to dry it well after the washing. It should then be covered with an ample rug, kept, as already stated, closely applied to its body by means of a roller or band of any kind. The bath may be repeated either on the same day or following days, according to circumstances. During and after the bath the animal should be allowed a draught of cold water, which helps to promote perspiration. The objects chiefly aimed at by the use of the vapour bath are to promote the circulation at the surface, to relieve the congestion of the *mucous membranes*, and to eliminate the poison from the system. Combined with the vapour bath may be used various other remedies not incompatible with it, but calculated to aid its action. Several of these remedies the committee now proceed to mention, it being, however, understood that only one of them is to be used along with the bath in each case were the experiment is made; they are not to be used together in the same case. A 1. Oil of turpentine.—This may be administered in doses of four tablespoonfuls, well shaken up with a chopin-bottleful of gruel, and may be given twice a day. This remedy may be expected to act beneficially by its powers of stimulating and of exciting perspiration. It may probably also, in most cases where it is used, supersede the necessity for giving any laxative medicine. A 2. Infusion of coffee.—The method of preparing this remedy is by infusing two ounces of ground roasted coffee for a quarter of an hour in a chopin-bottleful of boiling water. It must, of course be allowed to cool somewhat before being administered, and may be given in the above quantity every six hours. In addition to its stimulant and nutritive qualities the coffee may act beneficially in consequence of the empyreumatic oil and caseine which it contains. A 3. Carbonate of ammonia.—This medicine, which has been found in many cases to act beneficially as a powerful diffusible stimulant, may be administered three times a-day, in doses of half-an-ounce, either alone or preferably combined with three drachms of nitre dissolved in a chopin-bottleful of gruel. B. Acid treatment.—This treatment is suggested in consequence of the alkaline state of the secretions which is found to exist uniformly in the cattle plague. B 1. Dilute muriatic acid is said to have been successful in Holland. It may be given twice a day in doses of three drachms mixed with a chopin-bottleful of gruel. B 2. Vinegar.—This may be used in doses of 2oz., mixed with a chopin-bottleful of gruel, and may be given four times a day. C. Restorative treatment without drugs.—This consists in carrying out in full the sanitary instructions of the Royal Cattle Plague Commission—in regulating the diet according to the instructions already given—in keeping the animal warm, and in administering two chopin-bottlefuls of good Scotch sweet ale three or four times a day. It is desirable that this system should be carried out in a certain proportion of cases, all drugs being rigidly abstained from. D. Prophylactic treatment.—The committee would further desire to draw attention to the importance of experiments being made as to the efficacy of prophylactic (protective) treatment either in preventing the development of the disease or modyfying the intensity of the symptoms when the disease becomes developed in animals which have been exposed to the infection. In such cases, of course, all the sanitary measures of the Cattle Plague Commission should be strictly carried out. There may also be given at the earliest possible period prophylactic drugs, of which those most deserving of trial seem to be—D 1. Sulphite of soda given morning and evening, in doses of 1oz. dissolved in a bucketful of water. D 2. M'Dougall's solution, of which a wine-glassful in a bucketful of water, may be given twice a day. D. 3. A mixture of half-an-ounce of sulphate of snda and two tablespoonfuls of M'Dougall's solution, in a bucketful of water may be given twice a day. It would have been easy for the committee to have given a much longer catalogue of methods of treatment, but this would only have been embarrassing to practitioners. In the suggestions made they have sought to combine simplicity, safety, and economy. Whatever the results of the experiments may be, all of them may be easily and cheaply carried out under almost any circumstances. It should be borne in mind that the results of the experiments, whether positive or negative, will be important. The committee in conclusion, beg to invite communications as to the results of treatment from practitioners, and are prepared to give their best consideration to any plans which may be proposed for experiment. In name of the committee,

"ANDREW WOOD, M.D., Chairman."

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 30th ult.:—William Soltau Eccles, Granville square, W.C.; Algernon Ewen, Long Sutton, Lincolnshire; Theodore Fennell, Rainhill, Lancashire; John Waller Melson, Newhall street, Birmingham; William Evatt Wright, Witham, Essex.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 28.

Dr. ALDERSON, F.R.S., President.

A PAPER, by Dr. SAMUEL GORDON, describing a

CASE IN WHICH THE OPERATION OF TREPHINING OF THE SPINE WAS PERFORMED

was communicated, with observations, by Dr. ROBERT M'DONNELL. The case reported is that of a man, thirty-one years of age, who met with an injury of the spine on March 27, 1865. He was thrown from a horse into a ditch while hunting, and was immediately affected with paralysis of the lower limbs, rectum, and bladder. When admitted into the Whitworth Hospital, under Dr. Gordon's care, these symptoms still continued, a bed-sore had formed, and there was incontinence of urine, which fluid was alkaline, and contained copious mucopurulent deposit. One of the vertebræ in the lower part of the spine was displaced. The extent to which the spinous process projected was shown in a cast exhibited. Dr. Gordon performed the operation of trephining at the patient's urgent request on June 3. The operation lasted fifty minutes, and was not accompanied by much hæmorrhage. Soon after the operation signs of improvement were noticed. On the fourth day after it the urine became acid, but this condition did not continue; sensation improved, and some days later there was observed an increase of motor power. After some time the urine, which was sometimes alkaline, sometimes neutral, became permanently acid, power over the bladder was restored, and the patient was conscious of the passage of fæces. Within eight weeks he was able to go out, reclining in a basket carriage. He has now regained control over the bladder, and he can sit erect with ease and comfort; but he cannot stand, or of course attempt to walk. His general health is excellent. In making observations on this case, Dr. M'Donnell draws attention to the following points:—1st. There is nothing in the operation of a necessarily fatal kind; neither is it of necessity followed by exfoliation of bone, formation of matter, &c., which makes convalescence very tedious, if not impossible. and. He thinks that even those who do not advocate the operation in question must admit that in this case the operation was the cause of improvement. 3rd. Judging from our present experience, he recommends that in future cases the operation should be performed early, before structural change has taken place in the cord, and the muscles have fallen into a state of atrophy, from which it is difficult for them to recover. 4th. He advocates removing the posterior arches of more than one vertebræ as a proceeding which adds little to the difficulty or severity of the operation, and nothing to its danger, and which gives the patient a better chance of ultimately being able to stand and walk.

The PRESIDENT remarked that the paper just read was a beautiful specimen of caligraphy, and he hoped it would be taken as the prototype of future papers.

Mr. URE rose to return thanks for the author's very important communication. The case related was the first in which recovery had followed such a procedure. Mr. Ure referred to Mr. Cline's and to Mr. Tyrrel's cases. In the latter the injury was at the tenth dorsal, and after the operation the patient recovered sensation and motion, and could even to get out of bed, but died in a fortnight of peritonitis. Mr. Ure referred to a case by a French surgeon. The patient died on the fourth day after the operation. In the spinal cord was torn across and the bone much fractured. He agreed with Dr. McDonnell that it was important to operate early, and he thought where there was fracture with depression of one or more laminæ, attended with paraplegia and retention of urine, it was justifiable to trephine without hesitation. Mr. Ure then related a case recorded by M. Louis, in which paralysis of the lower extremities and retention of urine followed a bullet wound of the spine. The bullet was extracted, but the symptoms persisted. Some splinters of bone were then removed, and the symptoms passed off. Twelve years after the occurrence the man could get about with but slight difficulty. He (Mr. Ure) thought this case showed the necessity of getting rid of displaced bone when doing mischief. Dr. McDonnell's case proved that the operation was not so serious as it was generally supposed to be.

Mr. BARWELL thought the record of this case valuable, as proving that such an operation was not fatal, but he thought it proved nothing more. We knew, he said, that such cases do recover, and he related a case in point, in which the symptoms had been precisely those of the case related in the paper.

Mr. SOLLY was a pupil of Mr. Travers when Mr Tyrrel operated on the case referred to. Mr. Solly then said that Mr. Heckstall Smith knew the particulars of the case well. Mr. Travers, who was present at the operation, expressed to Mr. Solly afterwards his fears that the operation never would succeed, as the cord was always too much bruised to be capable of reparation. In consequence of his previous observations, Mr. Solly made a drawing of the cord after death, which verified Mr. Travers' observations. Mr. Solly believed that the opinions expressed by his senior at that time retarded considerably the adoption of the operation.

Mr. HECKSTALL SMITH said he had recorded the case in the Medico-Chirurgical Review for 1827. He had never ceased to take an interest in cases of this kind. There was but little surgery in the country, and he had not come across a case of the kind again; if he had, he would have performed the operation. In Mr. Tyrrel's case, the operation had been performed pretty much in the same way as this. The result led to the operation being discouraged, but it ought not to have done so. After the operation there was considerable improvement, especially on the second, third, and fourth days; but it was not so rapid afterwards. On the ninth day, pleuro-pneumonia set in; it was treated actively, and the patient died. He evidently did not die from the operation, nor from any lesion of the spinal cord, but from pleuro-pneumonia. In this case the condition of the urine alternated from acid to alkaline. Before this case had been published, it had been held that an alkaline condition of the urine always arose from decomposition, but in this instance he (Mr. Smith) had clearly proved that the urine was alkaline when secreted. Mr. Smith concluded by saying that he hoped Dr. M'Donnell's paper would lead surgeons to select cases and to operate.

Mr. SHAW considered the Society honoured by receiving so valuable a communication from across the Irish Channel; and as other important papers had been lately presented from the capital of Scotland, and we had expected one this evening from the western metropolis of England—Liverpool—the Society might without presumption be called the "British" Medical and Chirurgical Society. He had listened to the details of the cases with much interest. He was unwilling to appear captious, but neither of them touched on the very important point—the effects of trephining the spine (as it was incorrectly called) directly after the receipt of the injury. In the successful case, the operation was not performed till the second month after the accident. Now, during that time the vertebral column must have undergone essential changes; if the bones had not perfectly united, at least all the adjacent parts must have become consolidated by the processes of repair. And observation shows that when patients have passed through the first stages of the accident, and have lived long enough for the injured parts to acquire some solidity and firmness, their chances of surviving, although with paraplegia remaining, are greatly increased; the probable reason being that, as they can then be moved more freely in bed, and their positions more frequently changed, the bed-sores are more likely to be cured. Mr. Shaw next made some remarks on the anatomical structure of the spinal cord at the seat of the injury. In Dr. McDonnell's case the fracture was found, on dissection, to have been at the junction of the last dorsal with the first lumbar vertebra;

THE MEDICAL CIRCULAR.

WEDNESDAY, DECEMBER 13, 1865.

THE SCIENTIFIC INVESTIGATION OF THE CATTLE PLAGUE.

Having expressed last week our opinion upon the pretensions put forth by the homœopathists in reference to the treatment of the cattle plague, we have nothing further to add upon the subject, except to repeat our wish that every facility should be given to those gentry to conduct their experiments, although we have no anticipation that they will be followed by successful results. If, contrary to our views, homœopathy should really prove beneficial, and the fact should be certified by competent observers, we shall not shut our eyes to the truth from whatever quarter it may come.

But leaving such absurdities for the present, as being inconsistent with the gravity of the circumstances in which we are now placed by the prevalence and the increasing severity of the cattle disease in our country, we turn to the more serious questions which have been raised by persons really competent to form opinions on the subject; and, in the first place, as we think it of paramount importance to determine the nature of a disease before proposing measures for its treatment, we offer a slight sketch of the pathology, before noticing the therapeutical indications which seem to be legitimately deducible.

It must be admitted, we think, that the disease is decidedly contagious, and that it thus resembles some of our exanthematous and febrile diseases, although it is identical with none of them. The visible pathological conditions during life consist in an abundant secretion from the mucous membranes, both the gastro-pulmonary and the genito-urinary, and in an appearance of general exhaustion, under which the animal sinks. After death it is found on examination that the internal mucous membranes are marked by patches of redness and congestion in various parts, and that the epithelium is detached in many places. No specific alterations of structure, however, are found in those regions where characteristic changes are often observable in the corresponding diseases of the human subject; thus, Peyer's glands, which are invariably inflamed or ulcerated in typhoid fever, are found wholly uninjured in the bodies of animals suffering from the cattle plague, and indeed these glands in the latter case are found less conspicuous than in health. The glands in question serving in some manner, by their secretion, to promote digestion, are rendered useless in cattle suffering from Rinderpest, because the animals refuse food for some days before death, and as the function of the glands is lost, their structure diminishes in bulk.

Thus it will be seen that the cattle plague is not typhoid fever, nor can it be said to be typhus. It is not small-pox for it is not attended by the characteristic eruption of that disease. In the earlier stages, when the secretions are increased, it somewhat resembles influenza in the human subject, and at subsequent periods, when purging supervenes, it bears some analogy to dysentery, while certain appearances of congestion of the fauces recall a few of the appearances of diphtheria.

The above brief outline, in which we have carefully avoided noticing any points except those established by observation, will perhaps rather show what the disease is not, then what it really is; but still we have enough to prove to us that it is an epidemic and contagious malady, characterised by great depression of the system, and general congestion and softening of the mucous membranes, and sometimes perforation of the intestines. This perforation appears to be the result of the softening and is not to be confounded with that which sometimes follows as a consequence of typhoid fever.

Such then being the pathology of the affection, we turn with considerable satisfaction to the suggestions lately made by the Edinburgh committee on the cattle-plague, in reference to the prevention and treatment. In the document containing these suggestions we find nothing of a dogmatic character, but the committee merely sketch out several plans of treatment which they offer to the consideration of practitioners, and at the same time they invite communications as to the results observed, and express themselves as being prepared to give their best attention to any other plans which may be proposed.

The subject is of so much importance that we have given elsewhere in detail the suggestions of the Edinburgh committee, and we would only offer a few observations in regard to their suitableness and applicability. As the disease consists very materially in a congested condition of the alimentary canal, it is very properly, as we think, recommended that food should not be pressed upon the animals, and that the diet should consist of the lightest and most digestible kinds of nutriment, as gruel, linseed tea, and the like. Again, as cold is one of the chief symptoms of the disease, it is recommended to keep the animals in a regulated temperature, and to try the use of vapour baths and other methods for promoting perspiration, thus sustaining the warmth of the body and eliminating the poison from the system. The use of drugs is cautiously recommended, but it is further suggested that a restorative treatment without drugs should also be tried, and the comparative results recorded. With regard to the prophylaxis, some very simple suggestions are laid down, the administration of the sulphite of soda being recommended, together with McDougall's solution. The sulphite is useful by giving off sulphurous acid in the stomach.

While thus adverting to the recommendations of the Edinburgh Committee, we desire to state our opinion that no plan of treatment hitherto proposed can be considered successful, and our chief reason for expressing approval of the above suggestions is because they make no pretensions to infallibility. They are merely put forward as hints for the guidance of practitioners, and as we have before stated, they are founded upon reason and sound views of patho-

logy. The great and indeed only effective measure at present known for the removal of the cattle plague is prevention; and the Government should take the most vigorous measures to remove the causes of contagion by a strict system of isolation.

DR. RICHARDSON ON THE PREVENTION OF CHOLERA.

This subject may be studied under four heads: 1. What can be done by the Government? 2. What by municipal bodies? 3. What by the household? 4. What by the individual? The governments of England and Turkey could do something to stop the spread of the disease by the pilgrim hordes, if they would establish at certain seaports houses in which all cholera patients should be retained. Quarantine should be abolished, because it can never be made sufficiently effective. Government also could provide an Act, making it a punishable offence to dispose of infected clothing: in support of this necessity, it may be stated that in one case the whole of the infected bedding of several cholera patients was actually thrown into the Thames in 1854. Lastly, the Government might see that the rivers of England are not polluted with sewage. This work is now in hand. Municipal bodies ought to determine at regular periods the condition of the water supplied to their districts. This is done now in the parish of Marylebone by the Medical Officer of Health, and that very efficiently, and the practice is deserving of imitation by all vestries and local boards of health. The municipal authorities ought also to see that drainage is everywhere good; they should provide proper houses for vagrants, giving ample means for washing and drying clothes, and should supply the people with baths and other appliances for securing cleanliness. One duty, not before put forward, could be accepted by our local authorities. They ought to provide in every parish one or more rooms for carrying out the process of disinfection without destruction of infected articles. This could be easily carried out at public baths and wash-houses by having there a room charged with heated air. Again, the municipal body should provide public workshops in crowded localities in which the heads of families might work in health and comfort and relieve their crowded homes during the working hours of the day. Lastly, the municipal bodies would only be following an advanced and enlightened course in taking means to diffuse amongst the uneducated classes a knowledge of the laws of life and health. In the household it is right to see that there is at all times a sufficient supply of water, and that the water is free of organic impurities. In case cholera should break out in a household, the sick person should be placed in a separate chamber, and all infected articles, and the *excreta*, should be disposed of with scrupulous care. During epidemics every article of food that would bear washing should be carefully washed in water that has been boiled. As regards the individual, the great point to remember is, that the poison of cholera can only enter the system, to do harm, by its being swallowed. The individual should avoid cholera poison as he would prussic acid, or other physical poison.—'Social Science Review.'

THE METROPOLITAN SANITARY ASSOCIATION.—This Association intends to hold its first conference meeting on Monday evening, the 14th inst., at the rooms of the Society of Arts, John street, Adelphi. Thomas Chambers, Esq. Q.C., M.P., has consented to preside, and Dr. Druitt, President of the Association of Medical Officers of Health for the Metropolis, will deliver an address "On the Defects of the Existing Sanitary Laws, with Suggestions for their Amendment;" after which, discussion on the subject will be invited.

MEMORIAL TO A MEDICAL PRACTITIONER.—The Officers of Portsea Convict Prison have erected a memorial to the late Dr. Bowler, the surgeon superintendent of that prison. It is in the form of a marble cross over his grave.

CHOLERA IN NAPLES.

(BY THE CORRESPONDENT OF THE 'TIMES.')

NAPLES, DEC. 2.

As compared with the early days of November the cholera is reduced to infinitesimal proportions, and the public spirit is rallying rapidly, too rapidly perhaps, as many of those personal precautions which are at all times desirable are likely to be neglected. For the last two days of which I have seen the reports the cases have been thirty-eight and twenty-three, while the deaths have not been more than fourteen and twelve. The environs show also a similar improvement, as the cases on the same days have not been more than thirty-one and fifteen, and the deaths four and nine. Of those places Ponticelli and Torre del Greco are the greatest sufferers, and I regret to say that at San Giovanni, from which I reported such a grotesque outburst of joy, other cases had appeared. The probability is that the malady has spent its force for the present; the cases that now occur are as nothing compared with the vast population of Naples, and strangers desirous of visiting our city may return with impunity. "The malady," says a Medical friend,—

"Is rapidly on the decline, though I fear we shall not get entirely rid of it for a long time to come; perhaps it may linger on till the spring, and burst out again as it did during the first epidemics at Naples. On the whole, however, we cannot say that we have suffered very much, and certainly not so much as the filth and conglomeration entitled us to. I had only one fatal case, several cases of declared cholera, and a great many of diarrhœa, which would have become so if not taken in time. The more I see of the disease the more certain I am that its ravages might be entirely prevented by a house to house visitation, and an early treatment of premonitory symptoms which are scarcely ever absent. As to the treatment, this epidemic has again taught us nothing; many old remedies have been brought up anew, and puffed, such as quinine and quassia injections, chlorodyne and opium; but the result has been the same as in other epidemics—about forty or fifty per cent. of mortality of the *declared* cases, while the mortality from subsequent typhoid fever has been the greatest in those cases that have been treated by violent remedies, and chiefly by opiates and alcoholic stimulants. The disinfectants used chiefly have been sulphate of iron for the excreta, while the rooms, bedding, furniture, &c., have been fumigated with chlorine gas. In the military hospitals the rule has been that no one left the hospital (of the Medical and other attendants) before having remained a few minutes in a room exposed to those fumigations. The exemption of Sicily (and of Rome) up to the present time is certainly in favour of the complete *ex communicatory* system; but then, again, on the other side, Leghorn and Genoa have been exempted, though a quarantine of only a few days was insisted on."

In addition to this, it may be observed that the islands in the Bay, which, from their position, are cut off from close communication with Naples, have not been afflicted except in one or two cases, which were evidently carried over from the city. As to the quassia experiments, the results are not spoken of by the Medical men who made them with any sanguine feeling. What they say is, that it is premature to form any opinion of experiments made on the decline of an epidemic. In the Hospital of Piedigrotta two or three rooms have been set apart for non-Italian practitioners, English, French, German, Swiss, &c., and as my friend is engaged there his evidence is worth attention. In all the cholera hospitals the staff has been considerably reduced, but in a wise precautionary spirit the hospitals themselves will not be finally closed before next summer, as the experience of other epidemics threatens the possibility of a return. Naples has, however, been submitted to such a thorough sanitary investigation, the precautions taken have been so minute, and the public mind is so much more alive to the secondary causes of the malady, that on occasion of another visit the chances are that cholera would have to struggle hard for a footing. It is extraordinary that during the whole time that the city

has been suffering so much, I have not seen one word published on that great chronic source of all malady here, the infamous system or no system of sewage, yet the evil offends every sense, and, as my friend observes, Naples ought to have suffered a vast deal more.

MEDICAL SOCIETIES.

(Continued from page 421.)

and in Dr. Gordon's it was supposed to have been at the same locality. Now, that is the very place at which the numerous roots given off to form the cauda equina envelope the cord. And it is important to remark that these roots, by thus surrounding the cord afford it a great protection against injury. Accordingly it is allowable to suppose that in both cases the lesion of the spinal cord was not so severe as it would have been had the fracture occurred elsewhere. He (Mr. Shaw) had recorded four cases of fracture, with dislocation, at or below the second lumbar vertebra in which the patients had no paraplegia at all, and recovered. The explanation was that the injury had been committed below the point where the spinal cord ceases, and at a part where the cauda equina alone is contained in the vertebral canal. So it has been observed that in the majority of those rare cases in which the patients have been so fortunate as to have had motion and sensation restored, after they had been lost from fracture, the injury had taken place in the dorso-lumbar region—viz., near the point at which the cauda equina commences.

Mr. HOLMES COOTE said that, without expressing an opinion respecting the propable verdict of the Profession on the operation proposed by Dr. McDonnell, he yet thought that it merited the earnest attention of surgeons. All were aware how fatal were accidents combined with fracture of the spinal column ; it mattered little where was the seat of fracture—death so commonly ensued that a fatal issue was regarded as the rule. A specimen of repair after fracture of the spine of a Welsh miner, who lived several years after the accident, was once shown to him as a great curiosity and rarity. Under these circumstances, he thought the Profession indebted to those gentlemen who had brought the matter before the attention of the Society.

Mr. SPENCER WELLS agreed with Mr. Coote in his remarks upon the extreme rarity of recovery after severe injuries to the spine. In the course of his service in the Navy, and in the Eastern Hospitals during the Crimean war, many such accidents had fallen under his (Mr. Well's) notice, and he did not remember a single instance of recovery. Some lived several months in great misery, but he did not remember one patient who lived a year ; and such cases as those alluded to by Mr. Barwell and Mr. Shaw must be quite exceptional. The only instance of recovery he had met with was in a gentleman who met with a fall when hunting. Inflammation and caries of the intervertebral substances and bodies of three of the dorsal vertebræ followed, and paralysis, which lasted two years. But recovery was so complete that the gentleman lived for twelve years afterwards, married and had a child, rode, danced, and shot, and only died last year of Bright's disease. The spine (which was exhibited at the meeting) showed that the whole of the body of one vertebra and half of two others had been destroyed, and that these two were very firmly anchylosed. While this case proved the possibility of recovery, it was rather to be taken as an encouragement to Dr. Gordon and Dr. McDonnell that the man whose case was before the Society would completely recover power over his legs than as supporting the views of Mr. Shaw and Mr. Barwell in favour of non-intervention. It was very hard upon a surgeon, who might be blamed if an operation was not successful, to discourage him when it was successful by saying that the patient would have done just as well if he had been left alone.

Mr. WM. ADAMS thought the members were much indebted to the surgeons of Dublin for bringing this interesting and valuable case before the Society. In reference to the time which had been allowed to elapse between the accident and the operation—in Dr. Gordon's case this was two months—and the observations made by Mr. Shaw, it was certainly necessary to bear in mind the history of the paralysis in acute and chronic cases. The chronic cases, or those in which much time had been allowed to elapse between the accident and the operation, approached nearer to the cases of diseased spine and in these cases the paralysis as a general rule undergoes spontaneous and complete recovery in a period of from one to two years This Mr. Adams had frequently witnessed, both in children and adults, in cases of disease with angular curvature of the spine. In the case at present before the Society, Mr. Adams only regretted that the operation had not been performed at an earlier period. He should have no hesitation, in a case of fracture of the spine were there was compression, in trephining, or removing the posterior arches of the spine. It is true that the compressing cause is in front, and depends upon the displaced vertebral body, but the cord is compressed between this and the arches posteriorly, so that by removal of the laminæ the compression may be relieved. When the cord itself was not lacerated, as it is sometimes found to be in the more severe injuries, the prospects of relief from the operation were favourably, and the recent cases in Dublin were valuable additions to our knowledge of this subject.

Dr. R. MCDONNELL, in reply, observed that he was greatly gratified, not only at having been able to be present, but at the discussion which this case had elicited. He expressed some surprise that those who were opposed to operation in such cases had not laid more stress on the mechanical objection urged against it by Sir Benjamin Brodie in his well-known paper—viz., that as the body of the vertebra was, in the vast majority of cases, the seat of fracture, and as this part was out of reach, no good could be gained by operative interference. It was quite certain that in such cases it was only that part of the vertebra against which the cord is pushed back that could be removed ; it was only, in fact, possible to take away the counter-pressure. But this mechanical objection took no account of the cases which, although forming a very small proportion of the whole, yet sometimes occurred, in which the body is not broken, the posterior arch being the part fractured. Boyer had recorded such a case. While the operation of trephining the spine, as it is called, is set aside in practice, as it virtually has been, such cases must be lost which might otherwise possibly be saved. He did not conceive that any advocate for the operation would think of performing it in any case when the symptoms of compression of the cord did not exist. It would be less justifiable in such a case than it would be to trephine the skull when there existed no signs of compression of the brain. In reference to the case alluded to by Mr. Barwell, he could only say that the experience of those who had the largest opportunities of seeing such cases, as well as the shelves of the museums of Europe, showed how rare such cases were. In his own limited experience he had never been fortunate to see a case presenting such features as Dr. Gordon's case did just before the operation which had not run a fatal course. Dr. McDonnell did not think it probable that at a period of two months after fracture of the spine any considerable attempt at consolidation had taken place in most instances. It generally happened that the intervertebral substance was more or less lacerated, and the first thing nature does before setting about the work of consolidation is to absorb the lacerated intervertebral substance. This is always accomplished slowly ; and even when the patients lived five or six months after the injury, consolidation was sometimes found to have made but little progress. Dr. McDonnell hoped, and, indeed, from the character of the discussion on the case just detailed he hardly doubted but that some of the surgeons connected with the hospitals of this great metropolis, profiting by the experience of his own and of Mr. Gordon's case, would undertake to perform the operation in question, and he earnestly hoped that, improving upon what had been already done in this field, they might obtain successful results.

HARVEIAN SOCIETY.

THURSDAY, NOVEMBER 2ND.

DR. J. C. LANGMORE, PRESIDENT, IN THE CHAIR.

Mr. J. Z. LAURENCE exhibited

TWO PATHOLOGICAL SPECIMENS OF CANCER OF THE EYE-BALL.

In one of these cases the diagnosis was rather obscure, and the patient had been advised by on ophthalmic surgeon o have iridectomy performed. Mr. Laurence said that this peration was now so much in vogue that it would soon be ecessary to write a pamphlet to explain, not when it should e used, but when it ought *not* to be used.

Dr. TILBURY FOX read a paper entitled

REMARKS ON THE CHOLERA IN EGYPT.

The author explained that the object of his papers was o prove, (*a*) how untenable was the theory of spontaneous evelopment; (*b*) that the source of cholera poison was ndia; (*c*) the influence and great transporting power of hips, and currents of air; (*d*) the line of investigation re uired of the International Sanitary Commission; (*e*) the ction of good food as a preventitive—a word for the poor nd a warning to ourselves—and, lastly, the plan of pre ention and treatment found to be most successful of late; ll of which points directly concerned each member of ociety.

The author had recently visited Alexandria, Cairo, Jeru lem, Damascus, and other Eastern localities, and had en oyed admirable opportunity of investigating the circum ance which accompanied the recent outbreak of cholera Mecca. Cholera first appeared in Alexandria in a retched quarter, filthy to the last degree. Hot winds had revailed in Egypt during this year, and there had been a murrain among the cattle. The heat of the season had een special; 115° Fahr. in the shade in the day, descend ng to 60 at night. The water supply bad and scanty, even n the best hotels. Pilgrims to Mecca, the would-be Hadjis, 00,000 in number, all of them reduced to the lowest ebb f vitality by hunger, filth, and disease, and played upon y the exhalations of 700,000 animals (for each pilgrim was bliged to sacrifice one animal at the prophet's shrine,) ere congregated at Mecca. Cholera now appeared.

Was cholera generated *de novo* at Mecca? No—cholera s a peculiar and special poison, and generated independ ntly of the hygienic influences around the individual, but ttacking most those whose health is undermined by bad et, filth, &c. This cholera poison was clearly brought to urope from the East, and in the East from Mecca to Jidda, ence to Alexandria, Cairo, &c.; and there is sufficient ason for concluding that it was brought from India to ecca; for, previous to the outbreak at Mecca, several ves s arriving at Jiddah from India had lost many passengers m the disease; eighty died in one vessel. The transfer ce of the disease from India to Arabia illustrates the law action of poisonous diseases which require (1) a poison, a transference, (3) a suitable soil.

India was the nursery of cholera, and although the imes' newspaper had lately argued in favour of the nta neous generation of cholera, he, the author, was per ded that, like the *rinderpest*, cholera was contagious. e conductor of the plague from India to Mecca was the r Indian pilgrim, arriving half-starved, with an attack liarrhœa or semifever, at Jeddah, from the cholera hot . Burton mentioned that the cholera had visited dina four times before his visit in 1853. We cannot, refore, the author observed, refuse to see that the ten cy of every succeeding epidemic is to affect more widely range of country around, and that in any further out ak, we, in England, may anticipate a greater likelihood our own country being affected, if we are disposed (as ppears we are) to place less reliance than usual on rantine.

Besides the influence of individuals and ships, currents wind coming from infected localities would account for radic cases occurring at a distance from a focus of infec n; winds could carry the ashes of a volcano for forty or leagues. Fine sand had been seen on the sails of ships five hundred miles distant from the coast of Africa, according to Dr. Sedgwick. We often hear that cholera breaks out in places after a storm, or in a ship at sea when a stinking cloud has passed over it. The true and effectual check by which the epidemic might be strangled in its birth must be applied before pilgrims reached Mecca. There should be quarantine of all vessels arriving at Jeddah from India. It was the duty of England to see to this matter, since our India was the nursery of the disease and English ships brought it to Africa and Europe. Cholera appeared to be decreasing in France; but it may linger on the continent and enter England through Russia or Denmark in the spring. It is therefore necessary to be on our guard. Persons who committed excesses, whether rich or poor, were most liable to attacks in the late epidemic in Marseilles in August and September. Good food was an important means of keeping the disease at bay. Dr. Tytler had shown that the influence of bad rice had been well marked in the production of the disease in India, probably by affording a suitable nidus for the disease.

In quarantine establishments great care should be taken to give the inmates good food, as, too frequently, diseases of an epidemic character were fanned into flame by the miserable diet allowed on board of quarantine ships.

Dr. Fox then called attention to the unfortunate fact, that in case of any epidemic of cholera in the spring, the prospects of the poor in this country for this winter were far from cheering. The price of butchers' meat was high, and so were coals. The care of the poor was a sacred duty which the rich should not neglect, if merely on selfish grounds, and of what avail was it to preach sanitary views to the poor when their poverty prevented them from having sufficient food and warmth, &c. He spoke with praise of the dining-halls for the poor established under Lord Brougham's patronage.

Diarrhœa was not by any means necessarily an early stage of cholera. Collapse is independent of the diarrhœa in true cholera—although in chlorine it is not so—all drains and closets should be disinfected, a cholera belt should be worn, all attendants on cholera patients should wear respirators—a layer of silk is as good as anything—the nurses should also drink alkaline sulphites as antiseptics. In the East, cherry laurel water, opium, chlorodyne, and especially nux vomica, were used, and also for diarrhœa, acetate of lead, dilute sulphuric acid, with chloric ether, opium, and kino. The most successful plan has been that which aimed at restoring the force of the circulation by artificial heat, and controlling the diarrhœa. When the poison acts powerfully and produces collapse at once, stimulants are indicated, such as succinated spirits of ammonia; in medium cases stimulants are not required. Hot mustard baths, or hot air baths, with warm drinks are then useful. In cases of collapse, one-twelfth of a grain of strychnine has been given with good effect; or even one-fourth of a grain in more severe cases. Belladonna given freely internally is sometimes of use, and ice to the spine sometimes is beneficial. Frictions with oil of mustard, or aconite ointment with cajeput oil and turpentine stupes. He protested against the *indiscriminate* use of ice to the spine. For *thirst*, ice or effervescing draughts may be given. For sickness, cherry laurel water. As there can be no question that the dejections of cholera patients held the poison, alkaline sulphites may be administered as antiseptics. Concentrated broths and soups should be given and the sulphites put into these. Calomel in large doses has been praised; it probably acts locally, and the alkaline sulphites are much preferable, do more good, and no incidental mischief. *Salines* are not of any use; and although it is by no means certain that absorption is absent in collapse, yet, as it seems sometimes to be lost, the hypodermic treatment by salts of morphia seems indicated. By attention to early diarrhœal symptoms, depression and lowering of the pulse, the greatest benefit is to be attained. Still we must persevere unto the end in all cases.

Dr. FULLER observed that few of those present were so well qualified as the author of the paper, to speak of the origin of cholera at present, but for his part he could not believe that the arrival of a ship was necessary for the outbreak of epidemic cholera in any locality. Either the

incubation of the disease must be very long, or it might originate through local agency, and migrate independently of transportation. Thus, he had been informed by captains of vessels that weeks after their ships had been at sea, the cholera had broken out suddenly, and had ceased almost as suddenly. After the siege of Bomersund our fleet was perfectly healthy, and no cases of cholera occurred until the second or third day afterwards, when a stinking cloud came over the fleet, and thereupon the disease broke out in all the ships, and within a few hours many men had died of cholera. Again, with regard to the outbreak near Golden square, which Dr. Snow and others had attributed to the contamination of the Broad street pump-water by the secretions of cholera patients, he must say that he could not subscribe to this theory of the causation of the disease. Its appearance was astonishingly rapid; scarcely a case of cholera existed in the district until about six o'clock on the evening of the outbreak, and within the space of twenty-four hours not less than sixty or seventy persons had perished, and scores of others had been attacked with the disease. No drinking of the pump-water could account for such a rapid—nay, almost momentary outbreak of this epidemic; indeed, he did not give credence to the belief that the evacuations from the intestines of cholera patients had anything to do with the outbreak, for the pump-water was not suspected until after the disease had begun to subside in that locality, and it had been drunk by the inhabitants not only during the progress of the disease, but before the epidemic showed itself, and also during its subsidence when the water must have been excessively charged with the cholera secretion. Dr. Fuller went so far as to question whether the rice water secretions would produce the disease in any person, and expressed a wish that the experiment could be fairly tried. He would not be afraid to drink a pint of them. In fact, he for his part, did not believe much in the contagious nature of cholera. Again, some persons spoke of a contagion in the air, but the disease not unfrequently progresses from place to place against the wind, and that under circumstances which preclude the idea of the transmission by human agency. To avoid this difficulty, the theory of infusorial animalcules had been used; but glycerine traps had failed to discover these animalcules. After all sorts of theory, he felt inclined to attribute the disease to some telluric influence—some agency capable as electricity would be, of being transmitted through land and through water — acting on the organic nervous system, and so affecting it that all secretion ceases. He did not believe in any distinction between cholera and cholerine, the rice stools, and rice water vomiting, the cramps, the collapse, and the suspension of the urinary and other secretions were present in the one as in the other, and the cases differed only in their intensity and consequent fatality. He could not understand how bilious diarrhœa could be confounded with cholera, and he thought the word English cholera was a wrong one, since the disease was either cholera or diarrhœa, and could not be both. The term "sporadic" might be applied to cases occurring when the disease was not epidemic, but essentially these cases are identical with cases of epidemic cholera, and were characterised by the same symptoms. Dr. Fuller regarded the practice referred to by the writer of giving strychnine in quarter-grain doses, or extract of nux vomica almost *ad libitum* as erroneous in principle, and generally mischievous. So long as the state of collapse continued, it was indeed but of small importance what drug was used, or what quantity of it was given, as no absorption goes on during that stage of the disease; but if the unfortunate patient who had been drugged with large quantities of strychnine or opium survived this, the function of the stomach would return, absorption would commence, and he would then inevitably perish by the drugs of the doctor. His own experience of remedies in the collapse was that they were all in vain, and he would prefer himself, if he were in this state, to have only an occasional emetic, iced water to drink, rice to suck, a mustard bath, mustard poultices to the epigastrium, and friction with Cajeput oil or some stimulating embrocation to the extremities. Hot air baths had been praised, but the patient came out of them as cold as when he entered, and as far as he had seen, they were useless. During the early stages he thought much good might be done by dilute sulphuric acid in full doses, calomel and ice, cold water for drink, and mustard hot baths, and mustard poultices to the epigastrium. The application of ice to the spine, which had been much spoken of lately, is not new. In India cold douches to the back had often been tried, and proved very serviceable in allaying cramp, but not in curing the disease. In some cases warm douches proved most grateful to the patient. Neither, however, were of much value in a curative point of view.

Dr. D. MENZIES thought that some of the symptoms of cholera might be compared to the action of an acrid mineral poison, such as tartarised antimony. Considering that the coats of the stomach were in an irritable condition, he combined the decoction of bark with almond emulsion in the treatment of the first case coming under his care in 1831-2, when he was employed by government to watch the progress of cholera. The wife of a fisherman, aged forty-five, residing in an island in the North Sea at the mouth of the Elbe, had caught the disease from her husband, who had brought it from the mainland, from Hamburgh, although the man had only suffered from looseness of the bowels on the voyage. Dr. Menzies found the woman in collapse, apparently beyond hope: no pulse at the wrist, with jactitation as if in a case of loss of blood; rice-water stools; she had great desire for cold drinks; surface of the body cold and covered with a clammy sweat; voice gone. Dr. Menzies had recourse to the bark mixture above described, ℥j. at intervals. The patient gradually recovered the power of retaining food on the stomach. A pill was then given, calomel gr. v; pulv. op. gr. j; aromatic conf. gr. ij, and mustard sinapisms were applied to the epigastrum, with hot-water bottles to the extremities, and frictions, with diffusible stimuli. As the pulse, however, still continued to be absent, he opened a vein in the arm, but scarcely any blood would flow; but, by placing both arms in warm water, he was enabled to get away ℥v. of dark thick blood; about fifteen minutes after this the pulse was felt beating in both wrists. Under gentle mercurial laxatives she came round, and completely recovered. In other cases occurring in the island, he had found the same treatment satisfactory. He had generally observed when in the tropics during seasons of sickness, that thunderstorms were less frequent than usual, and that the atmosphere was oppressive. He thought that the poison of cholera acted upon the economy through the pneumogastic nerve, and the blood, becoming surcharged with carbon and wanting its serous part, failed to nourish the brain, &c.; hence the symptoms of collapse. Asiatic cholera was essentially a disease of hot climates and endemic in India, and was developed by the conditions of the atmosphere before mentioned. Much depended on the direction of the wind; for he had generally observed, that the disease was most prevalent when the wind was in the east; in 1855, when the disease was at Shorncliffe, having been imported thither by soldiers of the German Legion from Hamburgh, he had noticed that the wind was in the east when the disease was most severe. Although a non-contagionist, he thought the specific poison was undoubtedly frequently conveyed through individuals arriving from infected places, and that attendants on cholera-patients were not unfrequently attacked. Hence strict quarantine regulations should be enforced on vessels from infected places. Those attacked also should be perfectly insulated and a *cordon sanitaire* should be kept up. Troops may be removed from the infected district; great attention should be paid to ventilation and cleanliness, and water supply. The treatment of cholera which he had found most successful in India was the administration of small portions of iced water at short intervals. This often relieved the vomiting and thirst. Also a pill containing from five to ten grains of calomel with gr. j of opium, and gr. ij. of aromatic confection was given with effervescing draughts and diffusible stimuli; sinapism to the epigastrium, and hot bottles to the feet, with friction to the extremities. When reaction came on, mild mercurial laxations, nourishing food, &c. Care should be taken to keep the patient in the recumbent position, and the bed-

pan should be used. He (Dr. Menzies) laid great stress upon the quantity of iced water that should be administered. It should *not* be given *ad libitum*, but in quantities of a tablespoonful at a time. This refreshed and gave tone to the stomach. He found this treatment efficacious whether made use of in the earlier or later stages of the disease. In some cases there were no premonitory symptoms; in others there was premonitory diarrhœa. Referring to Dr. Chapman's views as to ice to the spine being of any service, he thought these were somewhat analogous to his own views, and he thought very well of the practice, since its object evidently was to stimulate the nervous centres, to relieve congestion, and impart tone to the nervous system.

Mr. SEDGWICK could not fully agree with the author's opinion respecting the transportation of cholera. He had himself had extensive opportunities of seeing the disease in India, and of hearing the opinions of Indian Medical officers on the subject; and whilst he agreed with the author of the paper that India might be referred to as specially connected with the source of the disease, yet it was impossible to account for its diffusion by the contagion theory alone, or to admit that the late epidemic in Arabia, Egypt, Syria, and elsewhere, could be satisfactorily explained in the manner suggested by Dr. Fox. The contagion theory of cholera was, to say the least, doubtful; and as an argument against it, Mr. Sedgwick mentioned a case in which four members of a family residing in a model lodging-house, consisting of eighteen sets of rooms, died from cholera excited by eating roast mutton in an almost putrid state. There were seventeen other families in the same building at the time, all of whom remained free from the disease. The rooms occupied by the cholera-patients were thoroughly cleansed with chloride of lime, fresh whitewashed, and re-papered, and left unoccupied for four or five weeks; but notwithstanding these precautions, two members of the next family who came to live in them, were attacked by cholera in a mild form, and recovered. The disease showed no tendency to spread, although there was but one staircase common to all the inmates, and no quarantine regulations were observed. Mr. Sedgwick agreed with Dr. Fuller that no internal administration of drugs was of use in the advanced stage of collapse. He thought that the hypodermic method of treatment might, to some extent, be available, and ought to be fully tried in the expected epidemic of cholera. Ice-bags along the spine would no doubt often succeed in producing reaction, but they might also do much harm, by inducing the secondary fever, which had been far more destructive than collapse in the late epidemics of the disease. Mr. Sedgwick referred to the absence of secondary fever in the first epidemic in India, and the almost universal treatment of cholera by bleeding at that period. Although there was now a prejudice against bleeding, yet it had been found extensively useful in this disease. He had often bled patients in the early stage of cholera with good results, the most urgent symptoms being relieved by it; and if this practice were revived, it would probably serve to lessen the tendency to excessive reaction, which had been the chief cause of death in the last two epidemics of cholera.

Dr. BROADBENT expressed his astonishment at the opinions advanced by Dr. Fuller, and especially with the grounds on which he had arrived at them. There was the fact, first, that in all the epidemics of cholera it had travelled from India westward in the track of trade and against the wind, which so clearly pointed to human intercourse as the cause of its transmission; he adduced a number of individual cases of its apparently unaccountable appearances at sea, its simultaneous development in certain districts of London, &c. Equally remarkable exceptions could be brought forward with respect to disease of the most decidedly contagious character, such as small-pox or typhus. In his opinion, when all possible allowance had been made for local causes and atmospheric influences, there was in the history of cholera epidemics something which could only be accounted for on the supposition of a specific poison transported by human agency. Dr. Fox had done good service by tracing cholera from India to Mecca in the last epidemic. The pilgrims assembled there were fit victims for any disease; but the condition, exhaustion, overcrowding, filth, however much they might predispose to cholera, were not those which produced this disease in its endemic habitat India. The impression on the organic system of nerves spoken of by Dr. Fuller, so far from being peculiar to cholera, was an effect common to all the specific blood poisons. As to terrestrial emanations, which had been suggested as a possible cause, no kind of analogy supported this idea. It was in fact confessing that we knew nothing about the cause, and it was better to say so in so many words.

Dr. C. DRYSDALE remarked that, notwithstanding the cogent arguments used by Dr. Fuller, he could not agree to the view that cholera was not contagious, although he would be only too glad to think the doctor right. Dr. Baly's analysis and the whole literature of the subject seemed to show that the only supposition fit to account for all the phenomena was that it was contagious, and that atmospheric or telluric or hygienic causes did not usually create the disease in Europe, but merely assisted its progress. He believed with Dr. Fox that it originated in India, and was carried by individuals to Europe. As to Dr. Snow's theory, he believed the truth to be that bad water of any kind much predisposed to diarrhœa and cholera, and certainly if cholera dejections were present, this must be reckoned the most dangerous of drinks. He did hope that Dr. Fuller would never make the experiment of drinking a portion of the rice-water stools, for however noble and heroic such like experiments were, they were too costly when such eminent lives were perilled by them. No one could fail to admire the heroism of M. Girard, the student at Montpellier, who placed fur from a dying cholera patient's tongue on his own tongue to encourage the attendants. The action was noble only because it was supremely dangerous. How did the non-contagionists account for the appearance of the late outbreak of cholera treading the very path that travellers most frequent—viz., from India to Alexandria, from Alexandria to Malta and Marseilles, thence by rail to Paris, and by boat to Italy? Then again appearing at Southampton on the arrival of a vessel there, and again in America on the arrival of an emigrant vessel. Dr. Baly and Dr. Simpson in Edinburgh, and Dr. Boeck in Christiania, had given the clearest proofs of the contagious character of cholera. In London and Paris, and large towns, it was very difficult to trace the origin of contagious diseases. No doubt it was desirable to prevent our people being terrified by the idea of contagion; but truth was always most advantageous for the mass, on the whole, than error. He would then, with Dr. Fox, urge upon European governments the importance of, if possible by quarantine operations and insulation of those attacked, restraining the ravages of what was now the most fearful scourge of the human race; and if the rinderpest could be, as it had been, so well kept out of south Europe by the German government, he did not despair of lessening the ravages of the cholera. With respect to the hygienic means of fortifying the constitution by good food, &c., he agreed with Dr. Fox that as long as poverty was so common as it still was in all civilised countries of Europe, little could be done in warding off epidemics. When the causes of poverty should be calmly considered and understood, instead of ignorantly and systematically ignored by those who ought, from their education, to know better, some hopes might be entertained that epidemics would in the end be less fatal. Attention to the size of families and emigration was of more importance than even ventilation, &c., since the very poor could never secure either good food, ventilation, or any other comfort. Every effort should be made to secure good drainage, ventilation, and food for the poor in the coming epidemic. With regard to treatment, the multiplicity of drugs used showed the difficulty of attaining great success with any, at particular stages of the epidemic. In cholera, as in other diseases, the rational treatment was always the best. Diarrhœa, if present, should be attacked by opium or sulphuric acid, and laudanum enemata should be used. M. Velpeau's advice—viz., to use five or six drops of laudanum every two hours on sugar, was good, and whatever remedy was used when the doctor was absent

should be as simple as possible. Strychnine, belladonna, &c., were, he believed, contra-indicated and very dangerous even in collapse, and warm applications to the extremities were the great remedies in collapse, with frictions over the body. Ice to the spine did not appear to him likely to be beneficial in collapse, although in diarrhœa it might do good. As to calomel, the empirical school was so devoted to the drug in every disease, that his expression of utter disbelief in any good it could do would have but little effect. Diluents were indicated from the extreme thirst and loss of fluids from the system; stimulants were frequently indicated. He agreed with Mr. Sedgwick that the hypodermic injection of morphia might often do great good in causing cessation of the evacuations. Dry cholera —*i.e.*, cases without diarrhœa—was most uncommon.

Dr. GREENHOW said that he should confine his observations to the point suggested by the last speaker (Dr. Drysdale)—viz., the contagiousness of cholera. He had carefully examined all the evidence adduced by various writers in support of the contagious doctrine, and had had peculiar opportunities for personal observation during the last two epidemics of 1849 and 1854, and yet no real instance of the spread of cholera by contagion had ever come under his notice. Many such had, indeed, been reported to him; but on a careful examination into all the facts every one of them had broken down. The strongest evidence in support of the doctrine of contagion was the general fact, that each severe visitation of cholera during this century had appeared to travel in a westward direction until it arrived in this country, but even this was, in his opinion, rendered inconclusive by various other facts which he should proceed to mention. The truth was that cholera was not new to this country in the present century, for it had prevailed here, although, as it would seem, in London exclusively, during the latter half of the seventeenth century, and had caused a larger mortality in proportion to the population of the metropolis than any of the visitations in our own time. The disease was so well described by Willis and Morton that no one practically conversant with cholera in the present day can doubt the identity of the two diseases. Then again, for several years before the advent of cholera to this country in 1831, there had been an increase in the mortality from diseases of a profluvial character in London, and no less than forty-eight deaths were recorded in the bills of mortality under the name of cholera in 1831, although the disease was not supposed to reach the metropolis until February, 1832. Also during the summer of 1831 several Medical men of reputation had published several cases of cholera that occurred in various parts of England some months before the earliest cases in Sunderland, where the importation of the disease into this country is supposed to have taken place in the month of October of that year. Moreover, there had not only been, annually, since that time sporadic cases which would certainly have been set down as true cholera had an epidemic been prevailing at the time, but there had been several isolated outbreaks which no one had attempted to attribute to importation from abroad. Neither did an investigation into the modern views as to the mode in which cholera is believed to spread by contagion afford any substantial evidence in support of the doctrine. These might all be said to be founded on the theory that the dejections of cholera patients were the exciting cause of the disease. According to Dr. Snow the swallowing of the supposed poison excites the disease just as the syphilitic virus excites syphilis. On the other hand, Dr. Thiersch considers that the dejections must have first undergone putrefaction to render them poisonous, and Dr. Pettenkofer that the dejections must act as a ferment in a porous soil already charged with night-soil in order to the production of the cholera miasm. These several views are, however, only theories which, although they tally in several respects with the local history of cholera, have never been brought to demonstration in particular cases, and all the evidence adduced in support of them amounts to the fact that cholera has prevailed especially where the people respired an atmosphere vitiated by the products of the decomposition of human night-soil, or drank water fouled by the like impurities. This fact was, undoubtedly, true, but it was not true according to his (Dr. G.'s) experience or investigations, that the presence was required in such impurities of the dejections of cholera patients, either in the recent or fermented state. Cholera being then in his opinion largely due to local causes, it might very properly be asked.—Why does not cholera prevail every year? To this he would reply—because at least another factor is needed. During and before every epidemic of cholera in the present century a certain meteorological condition has prevailed. The barometer has been high, the atmosphere remarkably still, the temperature, especially the night temperature, above the average and the rain-fall insufficient. It was also said that there had been a deficiency of electric movement. It was quite conceivable that in such atmospheric conditions both a different form of decomposition might take place, giving rise to unusual products, and that these latter would be retained longer in the vicinity of human dwellings. He could also conceive it possible that some other exceptional telluric influences might exist at such times. However this might be; cholera had come in 1831, in spite of a rigid quarantine; and he did think it most desirable that the attention of the Medical Profession, and of the public generally, should be directed rather to the removal of the local conditions, which appeared under every existing theory to be necessary to the spread of the disease, than to any attempts to prevent its importation by means of restrictions on commerce, which would certainly prove both futile and vexatious.

Mr. CURGENVEN was a believer in the contagious nature of cholera. We find, he said, the cholera following the course of trade. It visits Cairo, Constantinople, Ancona, instead of going to inland towns. Then it comes to Malta, then Marseilles, then Paris. Then to Gibraltar, and thence to Southampton, by the ship 'Nyanza,' on which vessel there were four deaths—yet she was only in quarantine one day. Some cases had appeared in London: one in a mantua maker who had come from Paris, and who died in ten days. Winter had come on and checked the disease; but it would reappear again in spring. Impure air and water would not cause the disease, but predispose those who are exposed to the contagion to take it. Certain epidemics will appear when a soil is prepared for them. Typhoid fever or cholera will ravage one side of a street with bad drains and leave the other untouched. In 1853, at the Royal Free Hospital, there was one nurse who evidently caught the disease from contagion. He had warned her after this against a second attack; but she met a cholera patient at the gate, took the disease, and succumbed. The poison of cholera was in the air in epidemic times, requiring only to meet a fit soil. Calomel was our mainstay in the treatment of the disease, ℈j., with gr. x. of powdered ginger, with + ℥j. of castor oil, and tincture of rhubarb after it. This treatment stopped the purging, and the patients got well. All recovered who were not collapsed before the treatment was used. The calomel was not absorbed. In 1855, in the Crimea, all treated by calomel recovered. In cases of collapse, camphor and opium were useless.

Dr. HART VINEN thought that the progress of cholera pointed to its contagiousness. He had seen several cases that strengthened this belief. E. G., a German baker, died of cholera. The woman who nursed him died of the disease, and several persons who came to see him died of it; the next door neighbours also died. In the time of the cholera outbreak of 1854, he had seen many cases where no alvine degretions could account for the disease. An old lady in St. John's Wood, who kept a school, was one of the first to die in that locality, and the curate also died. As to treatment, he had found calomel in large doses and astringents the best. The ordinary astringent of acetate of lead and opium was very useful.

Mr. OWEN had listened with great interest to Dr. Greenhow's address. Dr. Greenhow had shown that contagion was not necessary to the production of the disease. He (Mr. Owen) was, however, a contagionist, for he thought that that party had the best of the argument. It was hard to prove a negative; and all that the non-contagionists could say was that the disease might arise without conta-

gion. The disease in Epping lately was traced to a person who had been in Southampton where cholera was at the ime. As to the case of the student who swallowed the ice stools, not being infected, that was no proof that nother person would not be destroyed by it; his system ight be proof against the poison at the time. It was ell that there was a difference of opinion on the subject, s this caused the public to be less apprehensive, than if all ere contagionists.

Mr. ADAMS had been connected with St. Thomas's Hosital, in 1848-9 when there were cholera wards there. Mr. rainger's views were those of the non-contagiousness of the isease, and during the epidemic there was only one nurse ed, and none of the students died of the disease. Mr. Adams ade all the post-mortem examinations, and he could only y he did not think the disease directly contagious to inviduals, although the fact of its travelling from India emed hard to get over. No one at that time had any ar of contagion. Denudation of epithelium of the instines occurred in all the cases where collapse was complete. s to treatment, at that time all treatment seemed alike. o one had confidence in any drugs. A pailful of water the bedside for drink seemed the most successful. But hilst the epidemic lasted, no treatment availed anything er another.

The PRESIDENT had seen much cholera in 1832 in hitechapel, and small doses of calomel gr. ij. every ten nutes, with camphor and diluents and warmth to the remities had seemed to him to be of more service than y other line of treatment. He was still a contagionist, en after hearing all that Dr. Fuller and Dr. Greenhow d advanced. With regard to the example cited by Dr. eenhow of a town near Newcastle which was nearly expt from cholera, the same thing had often occurred in India. . Sedgwick's case he thought was one of contagion from walls of the room. Cholera always travelled the high d of trade. Influenza travelled quickly and probably sed by atmospheric influence. Cholera travelled very wly from place to place, just as travellers do.

Dr. MUSHET avowed himself a non-contagionist. Elevan above the sea explained the immunity of some dists over others which lay by the sea and in the course of de. In 1854, at the Marylebone Infirmary, all kinds of atment were used. Castor-oil treatment was always al. Sulphuric acid seemed the best. There was a night se in the cholera ward who lived in it constantly, and not attacked. Those who were attacked seemed to to have been so, because they were near the privies. the surgical wards a man and nurse died, who were a foul privy. The undertakers were not affected, and lived entirely among the dead. Another woman died , but she was a drunkard. He thought there was no cient evidence for the theory of contagion.

r. GREENHOW remarked that in 1854 every one was a contagionist, and now it seemed likely to be the reverse. l stinks were the supposed cause; now he could see Medical opinion had turned round towards contagion. o quarantine, it must be remembered that in 1831 antine existed and to no effect. He did not say that isease was non-contagious; but that he had not himeen evidence sufficient to convince him of the fact.

. TILBURY FOX in reply stated that he had recently ved information from the East corroborative of the l of the present epidemic in India. Before the pil- arrived at Mecca, it prevailed at Aden and Mokullah. ra, it was strange, was unknown in Australia. Con- was now differently defined from formerly. Thus, , a pilgrim, an animal, or a moist cloud from an incity might carry contagion.

IBRIDGE: INCREASE OF MEDICAL OFFICERS' FEES.—e weekly meeting of the Cambridge Board of Guardon Wednesday last, it was unanimously agreed to se the salaries of the district Medical officers. That . Knowles from 60*l.* to 80*l.*; Dr. Ransome's from 70*l.*; and Dr. Green's from 60*l.* to 70*l.* Of course crease is subject to the approval of the Poor-law

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board on the 6th inst:—Robert Wooding Sutton Barraclough, Streatham hill—diploma of membership dated April 20, 1865; John Henry Bryant, Sussex square—May 10, 1865; Fred. John Burge, L.R.C.P., Hammersmith—Nov. 15, 1865; John Davies, L.R.C.P., Ed., Leominster—not a member; Robert Charles Earle, Paignton, Devon—May 10, 1864; Samuel Geo. Freeman, Bolton row, Mayfair—April 21, 1863; Andrew Christopher Jackson, Cape Town—Nov. 14, 1865; Thomas Leigh, L.R.C.P., Chiswick—Jan. 21, 1863; John Loane, Dock street, Whitechapel—July 30, 1863; Henry Weekes, Brompton, Kent—July 26, 1865.

UNIVERSITY OF LONDON.—The following is a list of candidates who passed the late examination for the degree of M.D.:—Frank Buszard, Guy's Hospital; William Dale, Leeds, and Middlesex Hospital; Thomas Fairbank, St. Bartholomew's Hospital; Samuel Jones Gee, University College; Francis William Gibson,* B.A., University College; Gwynne Henry Harries, King's College; Charles Albert Hingston, B.Sc., St. Bartholomew's Hospital; Edmund Holland, University College; Horace Jeaffreson, St. Bartholomew's Hospital; Henry Law Kempthorne, (gold medal), King's College; Thomas Morton, King's College; Walter Rickards, University College; Eustace Smith, University College; R. Patrick Burke Taaffe, M.S., F.R.C.S. (exam.), St. Bartholomew's Hospital; Thomas James Woodhouse, St. Thomas's Hospital.

THE COMMISSION ON VENEREAL DISEASE.—In reference to the statement which had been published that the report of this Commission was on the point of publication, we mentioned last week that the report was not prepared, and would not be ready for some little time, although it was understood that the list of evidence to be taken was closed. At the same time we referred to the general conclusion deducible from what is known of the nature of the evidence given before the Commission. A distinguished witness, H.R.H. the Duke of Cambridge, has, however, this week consented to appear before the Commission. The Commander-in-Chief's opinions are generally understood to be as much in favour of an extension of the system of the examination and early treatment of soldiers and prostitutes as are those of others well informed on the excellent results which that system has had in restricting the extension of disease. We apprehend, therefore, that his evidence will only tend to strengthen the conclusion to which we have unofficially referred.—'Lancet.'

PRESTON NEW INFIRMARY.—The design for this building as prepared by Mr. Hibbert, is accepted by the committee. The number of beds in the western pavilion will be 68, the floor space averaging 110 feet each bed, and the cubic space nearly 1,900 feet. The cost is estimated at 8,000*l.* The plans contemplate the erection of an eastern pavilion at some future time.

THE QUEEN'S HOSPITAL, BIRMINGHAM.—A few friends of the Queen's Hospital met together at the Queen's Hotel, a few evenings ago, to entertain Mr. T. Thompson, late House-Surgeon, Mr. Jones, senior House-Surgeon, and Mr. Gideon Smith, Dispenser at the above institution, to dinner, upon the occasion of their retiring from the duties of their office. At seven o'clock a large number of gentlemen sat down to an excellent dinner. The usual loyal toasts were given, and speeches made in favour of the retiring gentlemen, who responded in an appropriate manner.

REMUNERATION OF MEDICAL WITNESSES.—At the Northern Assizes, lately held at Manchester, the grand jury, on concluding their labours, made a presentment respecting the small allowance to witnesses attending prosecutions, and more especially to Medical witnesses. They stated that in one important case which had come before them it had been proved that application had been made to no less than four Medical gentlemen in succession to attend

---

* Obtained number of marks qualifying for the medal.

the case, but they had all refused on the ground that they could not leave their ordinary practice to attend at the assizes for the small fees there allowed. His Lordship promised to forward the presentment to the Home Secretary, and observed that the public duty to attend and give evidence was confined to persons who actually happened to see the subject of the inquiry, and a man was not bound to take the trouble to make himself a witness. The allowances to witnesses, he said, was formerly very great, but it appeared now to have gone to the other extreme.

ALLEGED DEATH FROM CHLOROFORM.—An inquest has been held on the body of Mr. W. T. Davies, son of Mr. Davies of York Town, whose death was said to have resulted from an overdose of chloroform. Drs. Bradford and Collins, of the Royal Military College, attended the deceased until his death. They made a careful *post mortem* examination of the body, but discovered no appearances which would satisfy them as to the cause of death. There impression was, that death was produced by a narcotic, such as chloroform, or a similar agent. Dr. Cowan, of Reading, said that he was obliged to dissent from the opinion of the other Medical gentlemen, and to express his opinion that the deceased did not die from taking a narcotic. In consequence of this statement, when the inquest was resumed, the coroner adjourned the inquiry. Dr. Cowan said that he obtained the information on which he based his opinion from the father, sisters, grandmother, and two aunts of the deceased gentleman. It amounted to this: For the last two months, Mr. Davies had shown a state of health gradually tending to the unfortunate result which had happened. The symptoms characteristic of his condition were disinclination, gradually increasing to active exertion, a persistency to sickness of a character distinctly cerebral in its origin, and an indisposition to study, the heart's action seemed to give him great pain, and he knew he had disease of the heart. These had increased up to the day of his death. Mr. Davies said his son was twenty-five years of age, and, although not in actual partnership, had resided with him for two years since he had completed his studies. Of late he had been sick several times. He was of very temperate habit, and drank nothing but a little beer. He went to his son's bedroom on the Wednesday morning, when he found the door locked. Having forced the door open, he found his son in bed, loudly breathing; and on a small table near the bed stood a small tumbler and chloroform bottle. The heart was beating vigourously, and the surface of the body was quite warm. The jury returned the following verdict:—"That the deceased died suddenly, but whether from natural causes, or from taking an overdose of chloroform, the jury were unable to say."

THE BROMPTON HOSPITAL PATIENTS AT MADEIRA.—The twenty consumptive patients selected from those at the Brompton Hospital to winter in Madeira have arrived safely in that island. The steamer, 'Maria Pia,' whose second cabin was filled by the patients, sailed from London at two a.m. on November 8, arriving at Lisbon at ten a.m. on the 13th, having had a fair wind and fine weather the whole way, though a rough sea. In crossing the Bay of Biscay they experienced a heavy gale. To enable the invalids to recover from the effects of this, the superintendent thought it advisable to give them leave to go on shore at Lisbon for a short time, which did them a great deal of good. They left the Tagus on the 15th, at eleven a.m., and arrived at Madeira on the 17th, at 5.35 p.m. During the passage from Lisbon they had continued fine weather, and no sea. On the arrival of the steamer, Captain Erskine and Dr. Brandt came on board, received the patients with all possible kindness, and accompanied them to the Sanitarium, where they were comfortably quartered by 6.30 p.m. The invalids were visited the same evening by the Bishop of Sierra Leone, who read a portion of Scripture, and offered up a beautiful thanksgiving prayer for their safe arrival in Madeira. The accounts of the patients' health were favourable. Although there had been the average amount of sea-sickness, no spitting of blood had resulted from it, but, on the contrary, it was considered that the voyage had done them all good, and cleared their complexions. They appeared to have been well cared for on board, and spoke of the kindness of the two stewards who attended upon them. At the close of his letter the superintendent says: "I am given to understand that the British inhabitants in general of Madeira have contributed in furnishing the Sanitarium. The walls of the rooms are hung with most beautiful paintings; the furniture is first-class, and nothing is wanted in that line. I consider, jointly with my fellow patients, that our Sanitarium would not disgrace ony merchant in London as a residence." Prince Alfred was in the island when the mail left, and it was expected that his royal highness would visit the Sanitarium during his stay.

DEATH OF DR. HUTTON.—The general public and the Medical Profession have ere this heard with regret of the demise of Edward Hutton, M.D., which sad event took place on Friday last. This accomplished surgeon had been for some time labouring under a painful illness. Dr. Hutton had, after a long and successful career, attained to the highest rank in his profession. His advice was equally sought for as a surgeon or as a physician; a kind and courteous manner, combined with sterling ability, gained for him the regard and esteem of all with whom he came in contact socially or professionally. Dr. Hutton obtained the diploma of the Royal College of Surgeons of Ireland in 1819, and and was soon afterwards appointed Medical Inspector to the House of Industry, now the North Union Workhouse. In 1822 he became Surgeon to the Richmond Hospital, and in the same year took the degree of Bachelor of Medicine in the University of Dublin. He obtained the Fellowship of the Royal College of Surgeons in 1824, and the degree of M.D. in the University of Dublin in 1842. He was a President of the Pathological Society, and was in 1852 elected President of the Royal College of Surgeons. In the following year he became the Secretary to the College, which post he filled up to the present year. He was also Surgeon to Simpson's Hospital. He actively performed his duties in the Richmond Hospital up to last year, when he was appointed by the governors Consulting Surgeon to the Hospital. Dr. Hutton excelled as a skilful and successful operator; his contributions to the literature of his profession were numerous and valuable; and to his precepts and practice the Dublin School of Medicine owes much of its deservedly wide-spread celebrity.—'Dublin Medical Press.'

MEDICAL SERVICES.—The committee appointed to inquire into the causes which have for the last few years materially tended to prevent a high class of professional men from entering the Medical service of the army and navy, and to make a report which may, it is hoped, remove all existing difficulties, consists of the following:—Vice-Admiral Sir Alexander Milne; Major- General Lord F. Paulet, K.C.B.; Sir James Gibson, K.C.B., Director-General of the Army Medical Department; Dr. Bryson, C.B., Director-General of the Navy Medical Department; Captain Galton, Mr. Busk, and Dr. Markham. Mr. Robert Bell, of the Admiralty, is acting as secretary to the committee.—'Army and Navy Gazette.'

HOMŒOPATHIC TREATMENT OF THE CATTLE PLAGUE.—Mr. J. G. Marshall, of Leeds, on finding the cattle plague established in a cowkeeper's herd, took measures for placing the animals under homœopathic treatment in the most promising manner. The cows, seventeen in number, were lodged in sheds specially provided with all appliances for regulating temperature. They were given in charge to three professional homœopathists, two of whom were veterinary surgeons, and the requisite doses of "arsenicum" and other specifics were administered *secundem artem*. As eleven, however, out of the seventeen patients are already dead, and the others are not expected to live, we fear this particular experiment must be pronounced a failure.—'British Medical Journal.'

THE CATTLE PLAGUE.—From the papers received from the country, on Saturday evening, it appears that during the last week the range of the cattle plague has been extended in Cambridgeshire, though the deaths have in some places rather diminished in consequence of the prior annihilation of large herds. In the Yorkshire district the disease is still prevalent in the neighbourhood of Middlesborough, Malton, South Holderness, Beverley, Thirsk, and other places. It has not extended any further in Cumberland, but veterinary skill seems to have utterly failed to destroy it. In Norfolk there have been fresh outbreaks in the Erpingham Union.

Staffordshire also the disease has continued its ravages. e accounts from many other parts of the country are of equally gloomy character.

AT the monthly meeting of the Metropolitan Officers of alth, on the 16th inst., Dr. B. W. Richardson will bring ward his "Researches on the Origin and Nature of the isons which Produce Epidemic or Zymotic Disease."

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general nthly meeting held on Monday, December 4, 1865, Sir nry Holland, Bart., M.D., D.C.L., F.R.S., President, in chair, the Hon. Robert Bourke, the Viscount Cranrne, M.P., the Rev. John Henry Ellis, M.A., John ugh, Esq., Sir Edward Hilditch, M.D., and Stavely ig, M.D., were elected Members of the Royal Institution. special thanks of the meeting were returned for the itions to "The Donation Fund for the Promotion of perimental Researches." Lecture arrangements for the ing season:—Christmas Lectures, 1865 (adapted to a enile auditory): Professor Tyndall, F.R.S., six lectures, n Sound." Before Easter, 1866: Professor Tyndall, .S., twelve lectures, "On Heat;" Professor Frankland, .S., eight lectures, "On Chemistry;" Professor R. Westott, R.A., F.R.S., six lectures, "On the Way to Observe Fine Arts;" Rev. G. Henslow, four lectures, "On Strucl and Systematic Botany, considered with reference to ication and Self-instruction." After Easter: Professor nkland, F.R.S., four lectures, "On Chemistry;" G. arf, Esq., Secretary and Keeper of National Portrait lery, three lectures, "On National Portraits;" Rev. C. ngsley, M.A., two lectures, "On Science and Superstit;" Professor Huxley, F.R.S., twelve lectures, "On the siological Methods and Results of Ethnology;" Proor Ansted, F.R.S., five lectures, "On the Application of sical Geography and Geology to the Fine Arts." An a course may possibly be given by Dr. Du Bois Reynd, "On Electric Fish." The presents received since last meeting were laid on the table, and the thanks of members returned for the same.

BETHLEM ROYAL HOSPITAL.—The following remarks on foundation of this hospital are from a weekly journal: The Bethlem Royal Hospital was planted above six turies ago. It appears from Stow's 'Survey of Westster' that in very early times lunatics and distracted sons were admitted into a house near St. Martin's lane, a which they were sent to the Priory of St. Mary of lem, in the parish of St. Botolph Without, Bishopsgate, founded in the year 1247 by Simon Fitzmary, a en of London. In 1346 the house was taken under protection of the citizens of London, who, in 1546 based the patronage of Bethlem, and in the same year as included in the charter granted by Henry VIII. to Hospital of St. Bartholomew. Bethlem Hospital is cribed in the muniment book in 1632 as the house erein poor distracted persons are kept. One messuage y builded of brick at the charge of the said hospital, ining a cellar, a kitchen, a hall, four chambers, and a t, being added unto the old rooms. Item, the old , containing below stairs a parlour, a kitchen, two s, a long entry throughout the house, and twenty-one wherein the poor distracted people lie, and above eight rooms more for the servants and the poor to , and a long waste room now being contrived and in to make eight rooms more for poor people to lodge there lacked room before." It appears from Stow, n years later than this the house could not accome more than fifty or sixty patients, and he states that ospital stood in an obscure and close place, near many common sewers, and also was too little to and entertain the great number of distracted perboth men and women, who were sent there." After re of London the governors determined to build a ospital with more adequate accommodation, and a g, after the fashion of the Tuileries, was erected in elds, capable of accommodating 120 lunatics and dis persons, and the officers and servants necessary for duct of the hospital. The building which formed ntre of the Bethlem Hospital, and which was the isited by Mackenzie's "Mr. Harley," was completed in 1676. According to Stow the building was 540 feet long by forty feet wide, besides the wall which enclosed the gardens before it, which, Stow quaintly adds, "were neatly ornamented with walks of freestone round about, and a grass plot in the middle; besides which garden there was another at each end for the lunatic people, when they were a little well of their distemper, to walk in for refreshment." As years rolled on, and the population—and the proportionate number of poor distracted persons—increased, it was found that the hospital buildings in Moorfields, although repeated additions had been made to them, were insufficient as regarded extent of accommodation. The foundations, it was discovered, were upon loose rubbish and insecure; the whole building was "dreary low," and likely to induce "melancholia" in even sane persons, and another removal and enlargement was resolved on. An exchange was effected between the governors, who gave up about two and a half acres, the site of the old hospital, in Moorfields, and the corporation, for about eleven acres in St. George's Fields, upon condition that the governors should build an hospital capable of containing 200 patients, and appropriate not less than eight acres for their use, with liberty to employ the remainder for the general purposes of the hospital, and in augmentation of its revenue. The act for the erection of the present hospital was obtained in 1810, but the first stone was not laid until April, 1812, and in August, 1815, the building was completed. The hospital, as at first erected in St. George's Fields, cost about 123,000*l.*, which was met by parliamentary grants, 72,819*l.*; funds of the hospital 23,766*l.*; the Mercers', Grocers', Drapers', Fishmongers', Goldsmiths', Salters', Vintners', Apothecaries', and Cutlers' Companies 5,405*l.*; private individuals 5,709*l.*; the balance from miscellaneous sources.

HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK.—The new wing of this building is, by the permission of her Majesty, to be called the "Albert Wing." The committee have determined that the new wards shall at once be opened.

UNIVERSITY COLLEGE HOSPITAL.—His Royal Highness the Duke of Cambridge has consented to preside at the annual dinner of the University College Hospital, which is to take place at Willis's Rooms, on the 18th of April next.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, DEC. 13.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; St. Thomas's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Hunterian Society, 7½ p.m.—Council; 8 p.m. Dr. Ward: "Some Results of Acute Alcoholism, with Illustrative Cases; Microscopical Society, 8 p.m.—Mr. James Smith, "On a Method of Cell-Mounting."

THURSDAY, DEC. 14.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, DEC. 15.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, DEC. 16.—*Operations* at St. Thomas's Hospital, 9½ a.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.; Metropolitan Association of Medical Officers of Health, 7½ p.m.

MONDAY, DEC. 18.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metropolitan Free Hospital, 2 p.m.

TUESDAY, DEC. 19.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Pocket Formulary, and Synopsis of the British and Foreign Pharmacopœias. By Henry Beasley. London: John Churchill and Sons.

A Treatise on the Principles and Practice of Ophthalmic

Medicine and Surgery. Third edition. By F. Wharton Jones, F.R.S. London: John Churchill and Sons.

On Intra-Thoracic Cancer. Part II. By John Cockle, M.D. London: John Churchill and Sons.

The Introductory Address delivered at the Opening of the Medical Department of King's College, London, Session 1865-66. By W. O. Priestley, M.D. London and Edinburgh: W. and R. Chambers.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the Office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

SCRUTATOR. — It is quite true that in a review of Dr. Farre's edition of "Pereira's Materia Medica" in a recent number of the 'Lancet,' the reviewer takes the author to task for omitting all mention of many valuable drugs, among others, *podophyllin*. Podophyllin is not only comprised among the drugs in the British Pharmacopœia, but it is fully described in Dr. Farre's work.

DR. H. S.—We have received the newspaper, but the sentiments contained in the article alluded to are not in accordance with those generally entertained by the Profession.

ALIQUIS.—The use of what they call "auxiliaries" by the homœopaths is either an indication of dishonesty to their own class, or a proof that they begin to see the absurdity of the doctrines of Hahnemann. To pretend that a relief of symptoms is brought about by a decillionth of a grain of "nux," while half an ounce of castor-oil or a glyster is only an "auxiliary," is too monstrous a draft upon the credulity of rational beings.

MR. H. B.—The disease in question, although closely allied to cancer, differs from it in certain essential particulars.

INQUIRER.—We believe that the proposed plan has not met with much acceptance in this country, and we doubt whether it ever will.

DR. B.—The paper has been received.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 7S FARRINGDON STREET, CITY. Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.——Catalogue of Microscopes, &c., forwarded for 3 Stamps. Costly Illustrated Catalogue of Second hand Surgical Instruments forwarded for 6 stamps.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ¼ oz., 3s. 4d.

Dinneford's Fluid Magnesia,

now Perfect in Purity and Strength.

"Mr. Dinneford's solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

Sold in Jars for the use of Medical Men and Chemists, at 9s. 6d. per Gallon, Half-Gallon 5s. 6d., by the Manufacturers.

DINNEFORD & Co.,

PHARMACEUTICAL CHEMISTS,
172. New Bond Street, London,
and all Wholesale Druggist and Patent Medicine Houses.

Geo. Smith and Co.'s Pure Extract

of CALVES' FEET for INVALIDS and CULINARY USE. Sold in 6d., 1s., 2s., and 4s. packets. To be obtained of all Chemists, Druggists, Grocers, etc., and Wholesale at the Manufactory, 23 Little Portland street, Regent street Office: 94 Upper Thames street, E.C.

Pepsine and Pepsine Wine.—Boudault begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Chemist in Ordinary to the Queen and H.R.H. the Prince of Wales, 227 Oxford street, London, to whom all applications respecting it must be addressed.

Third Edition, with Further Remarks by Dr. CORVISART, Physician to the Emperor of the French, edited by W. S. SQUIRE, Ph. D.; published by J. Churchill, London; may be also had of the Author, 277 Oxford street, price Sixpence.

Quinine.—The Medical Profession—the LANCET—Dr. Hassall, and others, recommend "Waters' Quinine Wine" as an excellent and simple stimulant. Manufactured only by ROBERT WATERS, 2 Martin's lane, Cannon stree London, E.C Sold by Grocers, Italian Warehousemen, and others, 30s. a dozen.
Wholesale Agents, E. Lewis & Co., Worcester

Aloina.—T. and H. Smith, the

Discoverers of this,
THE CRYSTALLINE PURGATIVE PRINCIPLE OF ALOES,
(vide 'Edinburgh Monthly Journal of Medical Science' for Feb. 1851,) continue to prepare and supply it. They have the gratification of knowing that the most eminent of the Profession prescribe it, to the exclusion altogether of the various kinds of aloes.

Orders executed direct, or through any Drug House, by T. & H. SMITH and CO., 69 Coleman street, City, London and 21 Duke street, Edinburgh.

Medical Fixtures and Glass Manu-

FACTORY, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Altering in the above Profession, that he has an extensive assortment of SHOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc

Brass and Zinc Door - Plates.

—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges Chemists' Shops fitted up with Window-sill Plates in the plain or Gothic Patterns. Lists of Prices post free.

Plates altered and repaired.—Country orders punctually attended to.
36 CHANDOS STREET, CHARING CROSS. W.C.

LADIES' SURGICAL BELTS,

Abdominal Supporters, Elastic Stockings and Bandages, Rupture Trusses, Chest Expanders, Spinal Corsets, Instruments for Piles, Prolapsus Ani and Uteri, and every description of Mechanical Appliances, with all the latest improvements, are manufactured at reduced prices by

Mr. CHANDLER, 66, BERNERS ST., OXFORD ST., W.

A lady of great experience attends. Illustrated Catalogues forwarded. A liberal discount to the Profession.

H. Silverlock's Medical Label Ware-

house, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctor's Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.
YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles. Drawers &c.
SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.
LABEL CASES for the use of Surgeons, 14s., 18s., and 24s.
LATIN SLIP LABELS for Wholesale Druggists.
Catalogues sent on application.

Treloar's Kamptulicon,

COCOA-NUT MATTING,
AND OTHER DURABLE FLOOR COVERINGS,
67 LUDGATE HILL, LONDON.
Three doors from the Railway Bridge.

The Medical Circular.

SCIENTIFIC ARTICLES.

ANALYSIS OF A QUACK IMPOSTURE.

By Dr. Attfield,
Director of the Pharmaceutical Society's Laboratories.

I desire to bring before the members of the Pharmaceutical Society, chemists and druggists generally, and the public, an analysis of a substance which is stated to be cod-liver oil, in the form of an agreeable saccharine powder, but which does not contain a trace of that medicine.

This substance is sold in small flat boxes of two sizes, containing respectively about four and two ounces of a white powder, and having labels in French, the translation of which is as follows:—"Oleo-Morrhuine, or Saccharide of Cod-liver Oil; 6 francs or 5 shillings the box; 3½ francs or 3 shillings the half-box. This saccharine powder, by reason of the extreme division of the oil, is, in a very small bulk, more efficacious than all the cod-liver oils of commerce, as already proved by long experience. General depôt, Roberts and Co., Pharmaciens, 23 Place Vendôme, Paris; and Wilcox and Co., Chemists, 336 Oxford Street, London." Around the box is a label, also in French:—"Easy to take and more efficacious than the cod-liver oil of commerce, which often becomes prejudicial on account of the nausea which it inspires." On the inside of the box is another label: "Saccharide of Cod-liver Oil. This powder has the great advantage of being supported by all stomachs, and of easily assimilating itself in the organism. This precious result is obtained by the extreme division of the oil, whose elements (chlorine, iodine, bromine, phosphorus, and sulphur, &c.) are absorbed without repugnance, whilst the oil of commerce is rejected, and often becomes prejudicial by the nausea it inspires."

The obvious intention of these labels is to induce persons ignorant of the properties of oils to believe that the well-known Medicine cod-liver oil has been brought into a state of minute division by being mixed with a saccharine powder; that in this state it is so much more active, that a small dose will have as great an effect as a much larger dose of the oil itself; and that the natural tendency of cod-liver oil to become rancid and nauseating is prevented by the influence of the saccharine matter added. Any one, however, conversant with the characters of oil, must at once see that this nostrum cannot be what it is stated to be. For oil, minutely divided by the agency of a powder, presents so much surface to the air that it becomes rancid in a far shorter time than when in bulk; such a mixture would soon be so offensive to the nose and palate as to be utterly unsaleable. If to this be added the facts that the action of cod-liver oil on the system is *not* materially influenced by its state of division, and the amount of oil which can be added to powdered sugar without the latter losing its pulverulent form is so small, that a teaspoonful of the mixture would have no appreciable effect when swallowed, it must be evident that this so-called saccharide of cod-liver oil contains no cod-liver oil at all.

But if not cod-liver oil, what is it? It is nothing but powdered milk-sugar. A considerable amount of this sugar now extracted from milk, chiefly for use in the manufacture of homœopathic globules and certain varieties of infant's food; it can therefore be obtained readily and cheaply. A quantity costing a few pence is placed in a box, labelled so as to induce the public to believe that it is cod-liver oil in a concentrated, convenient, and palatable form, and forthwith sold for five shillings. Surely this is obtaining money under false pretences.

The method by which the analysis of this quack imposture was effected was simply the application of the ordinary chemical tests for saccharine bodies, the presence of one of which was indicated by the labels. That it was wholly milk-sugar was proved by ascertaining that a given quantity of it, dissolved in water, produced the same kind and degree and effect on a ray of plane polarized light as was exerted by a similar quantity of milk-sugar of known purity. "Chlorine, bromine, iodine, phosphorus, and sulphur, &c." were, of course, absent.—'Pharmaceutical Journal.'

ON THE ANÆSTHETIC AND SEDATIVE PROPERTIES OF BICHLORIDE OF CARBON, OR CHLORO-CARBON.

By J. Y. Simpson, M.D.,
Professor of Medicine and Midwifery in the University of Edinburgh.

At different times I have inhaled the vapours of various fluids besides sulphuric ether and chloroform, with the view of ascertaining their anæsthetic or other therapeutic effects. Several years ago I published some notes on the results obtained from breathing chloride of hydrocarbon, nitrate of ethyl, benzin, aldehyde, and bisulphuret of carbon. (See the 'Edinburgh Journal of Medical Science,' for April, 1848.) All these five fluids give off anæsthetic vapours, but in their manageableness and effects—and more especially in their after-consequences—they appeared to me to be very inferior to either chloroform or sulphuric ether. The same remark applies to other vapours which I have since tried, as those of kersolene, &c.

Lately I have inhaled and used a liquid the vapour of which seems to me to approach nearer in its quality and effects to chloroform than any other anæsthetic agent. The fluid I refer to is one of the chlorides of carbon.

In describing the products of the action of chlorine on one of the anæsthetic fluids mentioned above—namely, chloride of hydrocarbon, or Dutch liquid—Mr. Fownes states (see his 'Manual of Chemistry,' seventh edition, p. 445), that three or four chlorides of carbon can be artificially made from Dutch liquid by the abstraction of successive portions of hydrogen, and its replacement by equivalent quantities of chlorine. He enumerates as belonging to this series—1, Sesquichloride or perchloride of carbon (C_4 Cl_4); 2, Protochloride of carbon (C_4 Cl_4); 3, Subchloride of carbon (C_4 Cl_2); and 4, Bichloride of carbon (C_2 Cl_4).

The last of these compounds—the bichloride of carbon—is the newest anæsthetic which forms the special subject of the present observations. It was first, I believe, discovered by M. Regnault, in 1839. It has already received various appellations from various chemists, such as perchloroformene, perchlorinated chloride of methyl, dichloride of carbon, carbonic chloride, tetrachloride of carbon, superchloride of carbon, perchloruretted hydrochloric ether, and perchloruretted formene (see Gmelin's 'Handbook of Chemistry,' vol. vii., p. 355, and Watts' 'Dictionary of Chemistry,' vol. i., p. 765).

If it becomes, as I believe it will, for some medicinal purposes, an article of the Materia Medica, it will require to have a pharmaceutical name appended to it, and perhaps the designation of perchloroformene, or the shorter term, chloro-carbon, may prove sufficiently distinctive. In its chemical constitution, bichloride of carbon, or chloro-carbon, is analogous to chloroform, with this difference, that the single atom of hydrogen existing in chloroform is replaced in chloro-carbon by an atom of chlorine, for the relative chemical constitution of these two bodies may be stated as follows:—

Chloroform = C_2HCl_3.
Chloro-carbon = C_2Cl_4.

The chloro-carbon can be made from chloroform by the action of chlorine upon that liquid; and Geuther has shown that the process may be also reversed, and chloroform produced from chloro-carbon, by treating, in an appropriate vessel with zinc and dilute sulphuric acid, and thus exposing it to the action of nascent hydrogen. The most common way hitherto adopted of forming bichloride of

carbon consists in passing the vapour of bisulphide or bisulphuret of carbon together with chlorine through a red-hot tube either made of porcelain, or containing within it fragments of porcelain. There result from this process chloride of sulphur and bichloride of carbon, the latter being easily separated from the former by the action of potash.

The bichloride of carbon, or chloro-carbon, is a transparent, colourless fluid, having an ethereal and sweetish odour, not unlike chloroform. Its specific gravity is great, being as high as 1·56, whilst chloroform is 1·49. It boils at 170° Fahrenheit, the boiling point of chloroform being 141° The density of its vapour is 5·33, that of chloroform being 4·2.

Besides trying the anæsthetic effects of bichloride of carbon upon myself and others, I have used it in one or two cases of midwifery and surgery. Its primary effects are very analogous to those of chloroform, but it takes a longer time to produce the same degree of anæsthesia, and generally a longer time to recover from it. Some experiments with it upon mice and rabbits have shown this—two corresponding animals in these experiments being simultaneously exposed, under exactly similar circumstances, to the same doses of chloroform and chloro-carbon. But the depressing influence of chloro-carbon upon the heart is greater than that of chloroform; and consequently, I believe it to be far more dangerous to employ as a general anæsthetic agent. In a case of midwifery in which it was exhibited by my friend and assistant, Dr. Black, and myself, for above an hour with the usual anæsthetic effects, the pulse laterly became extremely feeble and weak. In another case in which it was exhibited by Dr. Black, the patient, who had taken chloroform several times before, was unaware that the new anæsthetic was different from the old; the pulse continued steady and firm, although she is the subject of valvular disease of the heart. The surgical operations in which I have used chloro-carbon have been, the closure of a vesico-vaginal fistula, the division of the cervix uteri, the enlargement of the orifice of the vagina, and the application of potassa fusa to a large flat nævus upon the chest of a young infant. In all of these cases it answered quite well as an anæsthetic. The child did not waken up for more than an hour and a half after the employment of the caustic, which was used so as to produce a large slough. Its pulse was rapid and weak during the greatest degree of anæsthetic sleep. One of the mice exposed to its influence, and which was removed from the tumbler where the experiment upon it was made as soon as the animal fell over, breathed imperfectly for some time after being laid on the table, and then died.

Chloro-carbon, when applied externally to the skin, acts much less as a stimulant and irritant than chloroform, and will hence, I believe, in all likelihood be found of use as a local anæsthetic in the composition of sedative liniments.

In two cases of severe hysteralgia I have injected air loaded with the vapours of chloro-carbon in the vagina. The simplest apparatus for this purpose consists of a common enema syringe, with the nozzle introduced into the vagina, and the other extremity of the apparatus laced an inch or more down into the interior of a four-ounce phial, containing a small quantity—as an ounce or so—of the fluid whose vapour it is wished to inject through the syringe. Both patients were at once temporarily relieved from the pain. The first patient told me her relief at the first application of the anæsthetic vapour was so long that she slept during the following night far more soundly than she had done for weeks previously.

The injection of the vapour of chloro-carbon into the rectum does not prove so irritating as the vapour of chloroform. In one case it removed speedily pains in the abdomen and back.

Chloroform vapour applied by sprinkling a few drops on the hand, and held near the eye, is one of the very best and most sedative collyria in some forms of conjunctivitis, ulceration of the cornea, with photophobia, &c. I have not yet tried the vapour of chloro-carbon, but perhaps it may answer still better, as less irritant, and almost as strongly sedative.

I have found ten or twenty drops injected subcutaneously by Dr. Wood's syringe repeatedly relieve local pains of the walls of the chest, abdomen, &c., without being followed by the distressing nausea so frequently the result of the hypodermic injection of preparations of opium and morphia.

Internally I have only hitherto tried it in small doses in gastrodynia, where it has the same effect as swallowing a capsule of chloroform.

The specimen of chloro-carbon which I have used was made by Mr. Ransford, who sent it down to Messrs. Duncan, Flockhart, and Co., of Edinburgh, under the idea that, by a chemical substitution, it might be converted into chloroform, and make a cheap medium for the manufacture of the latter drug. And perhaps I may be permitted here to remark that the quantity of chloroform used is now becoming very great, and might possibly be rendered greater if it could be produced at a still cheaper rate. We have two or three manufactories for chloroform in this city. The chief of these manufactories for it—that of Messrs. Duncan, Flockhart, and Company—now make upwards of 7,000 doses of chloroform every day, counting two drachms as a full dose; they thus send out nearly 2,500,000 doses a year. Are every two million and a half full doses which are used of opium, antimony, aloes, epsom salts, &c., attended with as little danger and as few ultimate deaths as these annual 2,500,000 doses of chloroform.—'Medical Times and Gazette.'

MEMORANDA OF THE MONTH.

FROM A CORRESPONDENT.

Amongst minor incidents of the month may be noted the steady attendance of Miss Garrett, the "lady apothecary," at the surgical operations of one of our chief hospitals, where, we are happy to see, she has been received with much courtesy and goodwill by the students. We cannot help seeing, however, many impossible and impassable objections and obstructions to ladies taking any high rank in the Profession, even as obstetricians.

Deaths from the chloroform "mixture," proposed by the London Medico-Chirurgical Society, begin to be noticed, so that we have perhaps not yet "got to the bottom" of these most deplorable accidents, nor do these mixtures, which are slow and uncertain in effect, prove an antidote.

The Societies have been engaged with (among other and many things) the interminable question of syphilis and its treatment. Dr. Boeck, who has been for the government prosecuting various experiments on "syphilisation," is about to leave London, transmitting the matter to safe hands, such as those of Mr. Lane, Mr. J. Hutchinson, Mr. Dunn, Mr. Coulson. The non-mercurialists hold their ground, but fear is expressed, that they are more of the nature of bookmen than of calm observers, who go from hospital to hospital, and for a dozen or twenty years have watched the two plans. It is wise not to judge of the proper use of mercury by its abuse; it is well to remember how phagedena is aggravated by it; such men as Skey, Carmichael, Drysdale opposing it as vigorously as Lawrence, Wormald, H. Lee, &c., advocate its use. Learned knights possibly looking at opposite sides of the same shield, according to an old and well-known legend.

The experiments on "syphilisation" for the institution of which Professor Boeck was invited from Norway by the Admiralty Commission, on the "contagious diseases" of sailors and soldiers, have now been going on for three months, chiefly at the Lock Hospital, Harrow road. A few, very few, cases of syphilitic women have been submitted to the remedy; the syphilisation from an original bad chancre, as we understand the learned professor, being renewed every third day, so that the amount of poison in the system becomes a "vanishing quantity," as they say in algebra, and finally disappears. Mercury is the one chief stumbling-block in the plan of cure by inoculation. Various opinions are hazarded on the feasibility of the plan, and practically

it was found almost impossible to carry it out at Guy's and St. Bartholomew's, where it was also tried, but we fear "found wanting."

The cases brought forward by Mr. Henry Smith at the Medical Society of London, on the 20th of November, gave rise to a very spirited and important debate, as to the alleged superiority of ligature in bad hæmorrhoids and prolapsus, over the clamp and cautery or *écraseur*. Mr. Lane, from a very large experience at the hospital for fistula and hæmorrhoids, as also Mr. Ashton bore witness to the extreme value of the ligature in large well marked piles; but there are many cases of small straggling piles; thickened mucous membrane; bad, ill-defined prolapsus, &c., where the ligature can not be so well applied, and here the general feeling of the Society seemed to be that Mr. H. Smith's clamp (a modification of the plan of Cusack, of Dublin) deserves more attention than it has received hitherto especially at institutions for this class of diseases. If there be a chance of much bleeding—there the ligature is best; it must not be forgotten, however, that tetanus has sometimes followed the ligature, and in the case immediately under notice, the death occurred from pyæmia after the ligature, a thing not conceivable under the clamp and cautery.

The paper of the evening by Dr. Anstie, on the "Sphygmograph," as already hinted, was rather curious than practical, singular or ingenious rather than of general every day adaptability to the difficulties met at the bed-side. On the walls the diagrams were rather curiously illustrative of the pulse in health, contrasted with the pulse in typhoid or typhus; where the force of the arterial wave; the occurrence of dicrotism, &c., in fever; the gradual settling down of the pulse to the health diagram in subsequent convalescence were all pencilled with startling force and accuracy. As we know now that wine is called for in fever where the *first* sound of the heart is weak, as we know the portentousness of quick pulse in doubtful phthisical and other cases, it is probable the sphygmograph in hospitals may yet become in good hands a useful aid in diagnosis or prognosis. It might be a question too, no doubt, *cui bono*, what is the use of multiplying difficulties for the young physician already "weighted" more than he can bear with histological, chemical, organico-chemical abstractions whose name is legion, one swallowing up another as one theory succeeds another.

The very remarkable tumour of the shoulder removed by Mr. Fergusson proved to be one of those recurrent fibroid growths that increase with such rapid strides; since they have commenced to grow, it had been growing only since June, all of the scapula and trapezius, all the clavicle external to the attachment of the sterno-mastoid, the entire arm and forearm came now to be taken away; the subclavian was first compressed, then incision made along the clavicle over back of tumour, two semilunar flaps quickly formed; the vessels not divided till the last moment, when happening to have a finger on the pulse, we found it to stop for about half a minute, partly due to shock, partly to the chloroform. The case, we are happy to say, has done remarkably well, and may be classed perhaps with a singular amputation, at the hip-joint by Mr. Gamgee at Birmingham, as a triumph of surgery.

REVIEW OF BOOKS.

The Elements of Prognosis in Consumption, with Indications for the Prevention and Treatment. By James Edward Pollock, M.D., Physician to the Hospital for Consumption and Diseases of the Chest, Brompton, &c. Pp. 432. London: Longman and Co. 1865.

Notwithstanding the numerous works which have appeared on the subject of consumption, the present is a very acceptable addition to the list. There are so many questions still remaining to be settled with reference to this malady, that any collection of trustworthy observations made with regard to its nature must be gratefully received, and more especially when they come from a physician who has carefully watched a number of cases as they present themselves in a large hospital specially designed for their reception. Dr. Pollock informs us in his Preface that his work is founded upon a minute study of cases at the Brompton Hospital, extending over ten years, and the numerous statistics given throughout the book show the diligence with which the materials at his disposal have been collected and arranged.

From the very title 'Elements of Prognosis in *Consumption*' and not pulmonary consumption, it may be gathered that the author considers the disease as a general or constitutional one, and not necessarily confined to, or originating in, the lungs, and this is the view held throughout the work. One of the early chapters, entitled "Phthisis, a Disease of the System," is devoted to the development of this idea, which is advocated at even greater length than seems to be necessary at the present day, when pathologists are pretty well agreed that the deposition of tubercle in the lung is only the local manifestation of a pre-existing taint of the system, and not a consequence of hæmoptysis, pneumonia, bronchitis, or other pulmonary disease. Still, as mistakes might arise from misapprehension on this point, Dr. Pollock does well to insist upon its being thoroughly understood.

Although phthisis is a strongly marked disease, and its symptoms are generally well understood, yet Dr. Pollock, from the facts he has collected, indicates the propriety of dividing it into several varieties, according to the natural characters it assumes. For this course he partly apologizes, on the ground of the tendency at present existing to break up pathology into fragments, but the excuse was hardly necessary, for such varieties as acute phthisis, ordinary phthisis, chronic phthisis, are well recognised in practice, and the distinctions existing between them are pretty generally appreciated. Dr. Pollock adds another variety, which he terms strumous phthisis, by which he signifies that form of the disease which occurs in strumous subjects, generally at a very early age, who present the tuberculous matter in the lung only as an accompaniment to the existence of the same deposit in other parts of the system.

The book is divided into twenty-eight, or rather twenty-nine chapters (for there are two chapters under chapter XIV.), the first three of which are preliminary, being devoted to general pathological considerations. The next chapter, to which we have already briefly alluded, regards phthisis as a disease of the system; the fifth chapter is on the duration of the disease, and Dr. Pollock remarks that considerable misapprehension has hitherto existed on this subject, and that phthisis is very often a far more chronic disease than is generally supposed, some very bad cases having survived or recovered from the disease, and others having tolerated the tuberculous deposit for a great number of years. Then follows a chapter on the premonitory stage of ordinary phthisis, and other chapters succeed treating respectively of acute phthisis, ordinary phthisis, and chronic phthisis, and strumous phthisis. Chapter XV. is headed "Age, a Modifier of Phthisis," and it contains many important observations, not only as to the age at which phthisis is most prevalent, but also as to the modification of the symptoms and of the duration of the disease by the influence of age, the chronic form being most common in old persons, and the acute in the young. Hæmoptysis is generally absent in cases of phthisis occurring in the old. Then the complications, antecedents, or accompaniments of phthisis are brought under review, as rheumatism, gout, disease of the heart, emphysema of the lung, asthma, chronic bronchitis, menstruation, pregnancy, lactation, hæmoptysis, gastric symptoms, diarrhœa, fistula, and pneumothorax. Chapter XXII. is devoted to the important subject of hereditary influence, a predisposing agent which is but too well understood, both by the Profession and the public. In this chapter, Dr. Pollock emphatically points out the great impropriety of allowing marriages to be contracted between phthisical consumptive persons, and shows how much might be done in the prevention of phthisis, if parents and friends, in deciding on this delicate question, were amenable to the arguments of reason and science, instead of being guided, as they generally are, by mere family or pecuniary

considerations. The "Preventive Treatment of Phthisis," which occupies two chapters, includes a number of judicious precepts for the rearing and education of children born of a consumptive stock, and for the selection of suitable occupations for persons with suspicious hereditary tendencies. The specific and direct treatment of phthisis in its different stages, occupies three more chapters, and the last is devoted to climate, a subject which is briefly but clearly and sensibly treated. On this latter subject Dr. Pollock writes with due reserve, remarking that it is impossible to cure tubercular disease by any change of air, and that the effects of climate are therefore only auxiliary means of modifying a constitutional disorder, which is not amenable to treatment by merely local remedies.

We regret our inability to do more than give the above very brief and hasty sketch of a book which is evidently the result of long and patient research in an institution, the records of which are rich in practical lessons; and Dr. Pollock, by the use he has made of the materials placed at his disposal, and by the practical and judicious conclusions he has been enabled to draw upon some very important subjects connected with the history of consumption, has conferred a great boon on Medical science and practice.

The Physicians', Surgeons', and General Practitioners' Visiting List, Diary, Almanack, and Book of Engagements for 1866. Upon a plan furnished to the Publishers by Francis Seymour Haden, Esq. Twentieth year.

This visiting list being now twenty years old, its merits are necessarily well known to the Profession, and in introducing it to notice for the forthcoming year we have only to state that, in point of neatness and portability, in goodness of workmanship, and convenience of arrangement, it is as distinguished as ever, and that it will commend itself to the notice of all classes of Medical Practitioners by the facilities it offers to all of recording their daily engagements, and accurately keeping their accounts.

"CYCLOPS'" THIRTY-SECOND LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—The fact of all those glands which are intended by Nature to secrete elements to be used again in the system, and according to their character and position being of very varied shapes and forms, as to lead to their being called complicated, shows that they are designed for manifold purposes, and these are of both an organic and inorganic nature. Organic, because they secrete vital elements to be used again, and inorganic because they use up, and otherwise appropriate a vast amount of non-vital elements; which are equally essential to the economy of the system. That they do this is shown by their structure being permeated by laminæ and fasciæ—which are, "prolongations of the skin or mucous membranes," all these parts being provided with ducts, to carry the combined secretions away. All this shows two distinctive actions most clearly and unequivocally. The first, that secretions are made from the glands themselves, which are basic salts, and secondly, that these are diluted with inorganic fluids, supplied from the fat which surrounds and permeates them everywhere. Now, fat in the living and vital state is kept in a semi-fluid condition, the more aqueous parts of which are constantly passing off in union with the true glandular secretions, while the more solid is maintained for the further formation of fluids. If this were not the case, it would be useless for the glands to secrete at all, for their elements could never get away. To show the impossibility of the blood being able to supply the diluents for this purpose, it has been calculated that there are from fourteen to twenty-eight pounds of blood in the body, more or less, which takes about three minutes and a half to make its circuit—that is, by the arterial circuit distributing its structural powers, and the venous blood carrying the residuary mass into the system again. Now, if as it is supposed, fourteen pounds of saliva alone are secreted in the body every twenty-four hours, how can this be obtained from the blood? Its natural currents would be stopped in a fearfully short space of time. Where, then, do other aqueous secretions of the body of equal or even greater quantity come from? Surely not from the blood! Yet, in face of all this, physiologists persist in saying, "all secretions come from the blood;" but add, "that it is a singular fact that new chemical compounds are formed in the secretions which are not known in the blood." No wonder everything is so apparently mysterious and singular. Not, however, in natural laws, these will always prove to be simple and clear as soon as they are properly elucidated. That which is really mysterious and singular are the theories and dogmas of schools, which I defy anybody to comprehend or understand. Now, it is well-known that if meat is deprived of its water, its valuable properties are destroyed, for in this case scarcely a fourth of its bulk and quantity would remain, and that which does, would be horn-like, tasteless, and perfectly unfit for food. Not less than three-fourths of the substance of animals and vegetables consist of aqueous diluents, which gave rise to Liebig's remark, "that a man's body might fairly be represented by a bucket full of water, with a lump of chalk, and another of charcoal." Thus, as I have previously said, the body must have powers to make its aqueous matters, independently of the blood. But the gases, having been ignored in a physiological point of view, and these being the only means by which these ponds and lakes and rivers are kept up, we have as a sequitur, the thousand false doctrines and dogmas, stopping the way to our better understanding, the economy of Nature. I have endeavoured to show how all these matters can be made more consistent with truth, by the natural formation of fat; by that fat being a retainer or reservoir of the fluids; by these fluids being the natural diluents of the basic formation of glands, and all those other elements made in the body to be used again by it, in the most consecutive and regular manner, entirely independent of the blood. But I will now show that there are other organs which secrete basic salts, and which could never be eliminated from the system unless it were for the presence of their natural inorganic solvents and diluents. These organs are the kidneys, and their secretion is the urine. Here again, it is most implicitly believed that all the urine is secreted from the blood, and there is no greater Medical heresy than to believe or assert anything to the contrary. Endeavouring to prove a bad argument, it is extraordinary what books tell us. *That* the rapidity of the blood circulation is sufficient to account for the shortness of time in which certain fluids reach the kidneys. Then again, it is said the kidneys are of a duller sensibility, and less energetic than other glands. Owing to the rapid passage of fluids through the kidneys, some other physiologists supposed a direct communication with them and the stomach. Anon a host of chemists injected the veins with the prussiate of potass; yet the astonishment was great, because it could always be found more in the urine than in the blood. Even coarse injections pass readily from the renal arteries into the ureters, and so they do into the veins as well. This was said to show the rapidity of the kidney circulation and the *possibility* of a sort of filtration or mechanical separation of the more aqueous portions of the blood. Then it is admitted that urine is the most complex in its elements, and most variable in its qualities of all the animal fluids. Foreign substances appear in it, and even change its composition and other fluids may disguise it altogether. Bile, fat, milk, blood, pus, appear in it, and so it is said the kidneys *reason less* on the sensation produced by the various substances in the blood, but often allows them to pass in a pure state. In short, the ancients considered the urine as a sort of extract of animal substance carrying off all that is impure in the animal economy. Then, again, modern chemists say that it is not merely the abstraction of a quantity of water and salts accumulated in the blood, which the kidneys perform, but that a chemical change is produced by them, either upon the whole blood, or some important parts of it. Even in a case recorded in the last century of an individual's bladder being turned inside out,

so that the flow of the urine through the ureters was watched, as well as the quantity and quality of the urine. In this there was noticed great differences, according to the state of sleep and waking and the quantity and quality of diuretic drinks. With all this, none could understand exactly the reason why such differences occurred, yet still it was believed, as it is now, that everything goes through the blood in some way or other. It never occurred to any physiologists, ancient or modern, that there could be two natural supplies from different sources, to make up the one urinous current. Notwithstanding this, it has been noticed that the urine in the ureters is turbid and imperfect, and the constituent parts, not thoroughly blended together, though it improves as it passes those ducts. One would have supposed that these discoveries would have led to other sources of supply; but it shows that when the mind is warped, how many subterfuges supply a given philosophy. The passage of the urine down the ureters, and the peculiar situation of these tubes in the musculo-membranous portion of the bladder, with the weight of the secretion above rendering the ureters always full, and one drop pushing another out into the bladder, never seemed to offer any suggestion that the due mixing in this passage from the kidneys to the bladder of the organic salts with an aqueous inorganic base, were or could be derived from two distinct sources of supply. Nor in the formation of these organic salts with their inorganic fluids, passing through the ureters, and then mixing again in the bladder, could be at all influenced by the mucous membranes of either. All these fair subjects for research and inquiry appear to have escaped observation entirely. The only philosophy permitted being that the kidneys purge the blood of something which would otherwise be deleterious to it, and the economy of the body generally. There is no doubt that urea is in a great degree a necessary element of the blood. It seems from the very position of the renal arteries that it is necessary to all the organs above them; for instance, the ascending aorta must carry to the contents of the thorax and the brain these essential elements, and the descending aorta doing the same to all the organs supplied with blood above where the renal arteries are given off. But below the renal arteries the only organs to be supplied are the genital. There are no others below compared to all above the renal, and no doubt the genital organs and lower extremities take an equal share of this property of the blood. But if it were not for the renal arteries there would evidently be too much; therefore it is that the kidneys are provided to abstract this extra quantity and so relieve the system. But physiologists are not satisfied with this, for they say the kidneys take all the urea and other salts from the blood, and somehow purge and purify it. If it really did this, I have calculated that we should require at least three pairs and a half of kidneys, instead of only one pair; one pair, for instance, ought to be situated immediately on the ascending and another on the descending aorta, and others elsewhere, but as this would be multiplying organs too much, there ought, then, to be three or four pairs of renal arteries from the above situations going to one pair of kidneys. I am merely showing the absurdity of the idea of what the kidneys with their present one pair of small arteries are supposed to do. Then, as to the urine itself, its difference, variety, and quantity does not depend on the blood circulation nor on the drink taken. Some persons are accustomed to make considerably less urine in comparison to the fluids they take; while others, on the contrary, make a considerable quantity more. Now, the kidneys are differently placed as organs secreting elements to be eliminated from the body, to the glands which have to secrete elements to be used again. These latter are so situated that they are constantly excited to action, while the kidneys are placed out of the way of all the chylo-poietic viscera, and are so shut off from them that they should have nothing to do with these acts, and moreover are surrounded with double and treble the quantity of fat to other glands. Whatever volume and quantity physiologists have given to the blood going from the renal arteries to the kidneys, they have done equal justice to the volume of the residuary mass coming from the kidneys by their proper veins, and have shown, if anything, that this mass is the greatest of the two; therefore, the system makes use of this diluent, minus its urea and other salts which the kidneys have extracted. The great fact of the highly-congeried state of the renal arteries ramifying on the kidneys, shows that they could not secrete the urea from this part of the blood except under very great pressure, and that they do this and leave other elements, clearly shows that we do not yet understand their true mode of action. What elements they do secrete pass through the bodies of the kidneys into their pelves, and must be of a highly concentrated character, for the veins have evidently run away with all serous elements and liquor sanguinus, and there they would be left if not released by other supplies of fluid to dilute and carry them off. The manner of their doing so I will explain in my next letter.

I am &c., CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

GENERAL CORRESPONDENCE.

To the Editor of the Medical Circular.

SIR,—I am sorry to see that Mr. Griffin's appeal to the Poor-law surgeons of England has not been responded to by them in the manner that it deserved. That gentleman's disinterested action has been applauded by the Medical Press, and appears to have been unanimously approved by all those most deeply interested in the movement. And yet (after the lapse of so many weeks), there is nothing done, no one to come forward to give him a helping hand in his honest work. What, then, is the reason of all this luke-warmnesss, this indifference? Is it that we have no grievances to be redressed? All, with one accord, must answer "No," to this question, and, indeed, have so replied for a generation past.

Have we, then, just cause to complain, and do we admit ourselves beaten?

It would appear so from the long silence of the many, and the sad want of enthusiasm manifested by the most of us. If we persistently say to ourselves that all efforts can be of none avail, then, indeed, we do resign our cause into the hands of our opponents, but this is surely not what men generally do, and least of all—Englishmen, educated Englishmen! I deny that a continuous and united effort must be fruitless in results. Never yet was it so in this world's work, and assuredly cannot be allowed to be in this particular instance. I will not believe that we are about to give up all that we have been seeking and asking for during the past ten years! Shall we lack energy and determination to go on and fight the battle until success is certain? No, we will not weary till the public and the legislature are made to know and feel the full extent of our wants, and the evils and sufferings of our poorer neighbours, nor ever rest until those wants be satisfied and those evils remedied.

Let us, then, come together, let us unite under our old and tried champion, and go forward in the right way. He has signified his willingness to remain at his post, and to continue the onerous duties of leadership. Let us not refuse our chosen man, and leave him single-handed in this emergency. No time should now be lost, the time for action is an important one, as he has pointed out.

Then, let us, without further delay come to his assistance. Money is required, nothing can be done without it, but money alone is not sufficient, we must be united, and thus render him moral aid.

Subscriptions should be immediately forwarded to Mr. Griffin at Weymouth, and he will then lose no time in calling us together, and taking the necessary steps to further progress, in the way which he so clearly pointed out to us in his admirable letter published in the Medical journals six weeks since.

I am, &c.,
WM. PROWSE.

Amersham, Bucks.
December 13th, 1869.

ABSORPTION OF MATTER BY THE BODY.

Whilst on the subject of the rapidity of the absorption of matter by the body, I may state that a French physiologist has observed that certain saline matters, such as iodide of potassium, nitrate of potash, or acetate of morphia, will pass in a few seconds through the whole of the system. Thus he was able to detect the presence of iodide of potassium in the urine three minutes after it had been taken by the mouth. But certainly one of the most curious instances published of late respecting the absorption of organic matters in the system is that related by Dr. Letheby, and which tends to prove the correctness of statements which have been published in former times, that certain chemists or persons had a secret of producing poisons, the action of which only became manifest a long period after they had been administered. Thus, Dr. Letheby states, in a paper which you will find in the 'Proceedings' of the Royal Society, and which contains some of the facts which he gave in evidence at a coroner's inquest in London, that the death of a person ensued twelve months after he had taken the substance which caused death. A man engaged in a large chemical works in London, had inspired, during his labours, a comparatively small quantity of a substance called nitro-benzine (now sold under the name of oil of bitter almonds, and used in large quantities for perfumery, and also for giving taste to various culinary preparations), and that this substance had gradually become converted into aniline (a substance now extensively used to produce colours, and also procurable from coal-tar), and had been the cause of the death of the man.

Paracelsus's Theory of Quintessence.

Although time is pressing, I cannot part from you this evening without calling your attention to the fact that every day we are realising the cherished ideas of the alchemist, and of the Medical men of the fifteenth and sixteenth centuries, who laboured, the one to extract from substances what they call the quintessence of them, and the other to apply what they supposed then to be such quintessences. From the imperfect state of science, chemistry included, at that time, they were unable to carry out what they conceived to be essential to arrive at a better and more enlightened treatment of disease. They perfectly felt that the extracts or infusions of the plants they had at their command had not a defined action in their treatment. All men of science know with what enthusiastic perseverance Paracelsus advocated the employment of quintessences; and although in his enthusiastic mind he went so far as to pretend that he carried in the head of his cane the elixir of life, there is no doubt that he and his disciples left a germ which has gradually grown to be a plant, and that the chemistry of the present day is gradually succeeding in extracting from plants their active principles. Although Medical men were convinced of the utility of employing the active principles existing in plants, as quinine, cinchonine (from cinchona bark), morphine (from opium), &c., still we had not a correct idea of the various actions which these diverse alkaloids exerted on the system. We are, therefore, much indebted to M. Claude Bernard for his admirable researches on the therapeutic action of the alkaloids of opium; and owing to his extensive physiological knowledge, as well as his perfect mode of carrying out his experiments, he has proved that we can class the action of the alkaloids of opium under three heads, as shown by the following table:—

THE ALKALOIDS OF OPIUM.

Soporific.	Convulsive.	Toxic.
Narceia.	Thebaia.	Thebaia.
Morphia.	Papaverine.	Codeia.
Codeia.	Narcotine.	Papaverine.
	Codeia.	Narceia.
Not Soporific.	Morphia.	Morphia.
Narcotine.	Narceia.	Narcotine.
Thebaia.		
Papaverine.		

These researches thoroughly prove the correctness of Paracelsus's views, showing that in the employment of opium due consideration should be given to the fact, that in the opium there are various agents acting in a defined manner upon the organs of the patient.—Dr. Crace Calvert's 'Cantor Lectures.'

MEDICAL SOCIETY OF LONDON.

PRESIDENT'S SOIREE.

This *soirée* was held at the Hanover Square Rooms, on Tuesday evening, December 12. The company, who were urbanely received by the president and Mrs. Baker Brown, were so numerous that before ten o'clock the rooms were crowded. In addition to objects of the usual kind, the tables and walls were furnished with many articles of *vertu* and fine art, which added much to the interest of the evening. Thus, decorating the walls, or lying on the tables, were —oil pictures by A. Solomon, Millais, R.A., Lee Bridell, Calderon, A.R.A., A. Moore, and Johnston; drawings by Topham, S. Solomon, and E. W. Cooke, R.A.—all lent by the Secretary; oil pictures by E. Frère, F. Walton, and W. Gale; water colours by David Cox, Laurence, Duncan, W. Hough, and J. C. Reed, lent by Mr. Crofts, of Old Bond street; a number of choice lithographs, lent by Messrs. Day and Co.; the life-size photograph of Chang, &c. on the tables were photographs from the London Stereoscopic Company, by Mr. Smallcombe and others. Mr. H. Swan exhibited a number of very pretty and striking crystal cube miniatures. There were also a number of Medical portraits, lent by Mr. Fitt of Old Bond street, and an interesting collection of portrait medals of Medical men and philosophers. Two exquisitely-carved marble heads by Leonardo di Vinci, and a terra-cotta bust of Michael Angelo (1520), were exhibited by Mr. Joseph, of New Bond street. Egyptian, Byzantine, and Etruscan ornaments, bronzes, and sculpture, exhibited by Messrs. Watherston and Son; specimens of sculpture, exhibited by Messrs. W. H. Bensi and Co., Regent street; rare china, parian, and glass lent by Messrs. Sharpus and Cullum; a collection of antique watches, lent by Mr. Benson, were also exceedingly interesting. Mr. Harry Emanuel exhibited an immense opal "the Idol's Eye," and other very expensive articles of jewellery which attracted much attention. Microscopes were exhibited by various makers, those with binocular arrangement largely predominating. On Mr. Collins' table there was a binocular dissecting microscope (Dr. Lawson's) of a simple and novel structure in which the plan of the refracting stereoscope, as regards the lenses, is reversed. Some excellent specimens of trichina spiralis were lent for exhibition by Dr. Thudicum. A great variety of Surgical instruments was displayed, and at the head of the staircase leading from the refreshment-room the spring bed, invented by Mr. Hamilton, of East street, Manchester square. This new patented bed is remarkable for simplicity, strength, elasticity, salubrity, economy, and cleanliness, and is said to have had extraordinary success in France. Messrs. Savory and Moore made a pretty display of crystallized and rare pharmaceutical products, among which were conspicuous crystals of chloride of chromium and boro-tartrate of potassa. Madame la Baronne de Lavenant exhibited specimens of her process for coating iron and other metals, and preserving them from oxidation. This invention of the Baroness de Lavenant is calculated to supply an important desideratum in the industrial world. In this age of iron, the absence of some efficient means of protecting the metal itself from that deterioration to which atmospheric agency inevitably exposes it has been sensibly felt, and many have been the attempts to accomplish this end. It will be curious, if to a female, and that a lady of rank and a foreigner, the merit of solving such a problem, which has baffled the genius and inventive faculties of those who, in our foundries and workshops, are directly interested in, and occupied with, the material to be defended, should be ascribable. Mr. Piesse exhibited a number of perfumes in bottles, each labelled with a note of the musical scale, according to his fanciful conception of their position in a gamut of odours. Crane

ınd Co. lent a large piano-mécanique, on which several pieces were performed by merely turning a handle, and thus causing a music board of raised brass pegs to move over a suitable arrangement for striking the notes. Rarely, we believe, has any *conversazione* gone off so successfully. The Medical Society owes its cordial thanks to the President, who had evidently spared no pains to make the evening pass with pleasure and interest to all invited.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, NOVEMBER 21.

DR. PEACOCK, President.

Dr. CRISP exhibited

SPECIMENS, DRAWINGS, AND WAX PREPARATIONS OF SHEEP PLAGUE,

y way of contrast with the same disease in the ox. He aid he had examined, in October last, in Norfolk and uffolk, twenty-eight sheep affected with this disease. He ad seen healthy sheep that had been affected when turned mongst diseased sheep, and had examined the viscera of sheep that died after inoculation from the ox; and there ould be no question about the identity of the affection. he chief points of difference in the morbid appearances ere the absence of the dry state of the food in the first nd third stomachs of the sheep, the less definite character f the spots, the absence of the swelling and redness of the eocæcal valve, the general absence of spots on the lips, heek, tongue, and palate, and the greater detachment of ıe epithelial coats of the stomachs. Most of the sheep xamined had soft and granular livers; but this lesion robably existed before the attack. The blood in all these ieep was so fluid that after death the uppermost eye was loodless, whilst that nearest to the ground was very ascular; and so with many other parts. The stellate ppearance of the blood-corpuscles, depicted by Dr. Smart, f Edinburgh, had never been seen by Dr. Crisp in this isease, either in sheep or oxen. He had named the plague he "Malignant Spotted Fever of Ruminants," as, judging om the many animals of this class he has examined, there as no other disease attended with a like eruption, and he ad reason to believe that all ruminants might be affected. le spoke of the inconsistency of the recommendation of ıe Commissioners, which advised the stoppage of cattle ıd allowed sheep free movement.

Mr. J. Z. LAURENCE exhibited a

MELANOTIC TUMOUR OF THE EYEBALL.

he tumour had been progressing two years before the tient, a woman, aged fifty-six, consulted Mr. Laurence at e Ophthalmic Hospital, Southwark. Below the cornea as a greyish, hard tumour; the iris was in contact with e cornea; the pupil was blocked up by a calcareous lens; ıe mobility of the globe was normal. Mr. Laurence moved the eyeball, the pain in it having become extreme. ıe eyeball was filled with a tumour, partly melanotic, rtly encephaloid, with all the usual microscopic chaters of cancer. The optic nerve, where divided in the eration, was neither discoloured, nor swollen.

Mr. J. Z. LAURENCE also exhibited an

ENCEPHALOID TUMOUR OF THE EYEBALL.

ıe patient, a woman, aged thirty-four, first consulted Mr. urence in June, 1864, for amblyopia, of two months' ration, of the right eye. This, examined by the ophthalscope, presented all the appearances of retinitis, with rtial separation of the retina. In six months the patient urned quite blind, the pupil being occupied by a grey ded membrane—detached retina—over which ran some eedingly atrophied vessels. The patient subsequently t ophthalmitis, for which she consulted another Surgeon, ıo performed iridectomy. In October, 1865, she again ısulted Mr. Laurence. The right eyeball was then unirsally inflamed. The left eye was irritable and amblyopic, power of vision being reduced to one-tenth the normal standard; its fundus cloudy; the optic papilla hyperæmic. Mr. Laurence removed the right eyeball on account of the sympathetic inflammation of the left one. To his great astonishment, he found the removed globe the seat of intra-ocular cancer. In the anterior and lower part of the globe was a mass of ordinary encephaloid cancer; in the upper and posterior part was a spherical cavity filled with an aqueous fluid; around the lower part of the encephaloid part was a layer of a fibro-plastic tissue. Mr. Laurence considered the case interesting, in consequence of the failure of diagnosis and of the rarity of white cancer of the eyeball in adults. This was the second case he had met with in eleven years.

Mr. HULKE thought the diagnosis might have been made, had the tension of the globe been taken into account. According to v. Gräfe, this was increased in separations of the retina from encephaloid cancer.

Mr. LAURENCE'S notes of the case, immediately before the operation, described the globe as "very soft." This, he thought, was explicable from the cavity of fluid behind the tumour, and showed that v. Gräfe's rule was not universal.

Dr. ANDREW exhibited a specimen from a case of

EMBOLISM OF THE PULMONARY ARTERY.

A woman, forty years of age. Her toes had been crushed by the wheels of an omnibus which had been passed over them. Mr. Paget removed them October 15. She went on well until October 2L, whon she had pain in the epigastrium and faintness. Brandy was given, and she fell to sleep again. Next day she felt as usual; but her skin was cold and clammy. At night she had a return of the violent symptoms. She became pale, cold, her pulse could not be felt, and she died in three hours. The pulmonary artery was found to be obstructed by a dark red clot built over smaller white masses. No old clots and no pus were found in any of the veins of the injured limb. But on looking into distant veins, such as the mesenteric and the cerebral sinuses, small similar white masses were seen which had not the ordinary characters of blood clot, but consisted of aggregations of white blood cells. Dr. Andrew suggested that this case gave some grounds for the supposition that emboli might be derived from the corpuscular as well as from the fibrinous constituents of the blood.

Dr. TILBURY FOX exhibited several

COLOURED PHOTOGRAPHS OF PATIENTS SUFFERING FROM SKIN DISEASE.

Dr. FOX said: The half-dozen illustrations, nearly life-size, of photographs of skin diseases are kindly placed at my disposal for exhibtion to the Society by Mr. Erasmus Wilson. I think it will be allowed that they are most truthful representations of actual facts, exhibit no contradiction between the colouring and the magnitude of parts; whilst they pourtray the finer and more delicate expressions of disease; and I would leave them to speak for themselves rather than spoil them by further comment. The first is a case of scrofuloderma; the second, lupus non exedens; the third, epithelial cancer of the parotid region and ear; the fourth, a case of cure of lupus exedens; the fifth, syphilitic melasma—a charming illustration of the peculiar wasting of muscles, the earthy hue of the skin, and the pigment staining; the sixth represents another view of case number one. They illustrate admirably the use of photography in securing a correct outline and adjustment in the proportion of parts.

Mr. BARWELL showed a photograph of a

CASE OF EXFOLIATION, AND OF A CASE OF EXCISION OF THE METACARPAL BONE OF THE THUMB.

The photograph showed the same appearance in excision and in what might be called artificial excision by disease. Mr. Barwell described the steps of the operation in his patient's case; the result was satisfactory.

Mr. BARWELL also exhibited a specimen of

CARTILAGINOUS TUMOUR FROM THE TENDON OF THE RIGHT FINGER.

In the operation, Mr. Barwell tried to remove the growth by a subcutaneous incision, but was obliged to open the sheath and dissect it from the tendon. The result was good. Mr. Barwell remarked that M. Malgaigne had said

(Continued at page 444.)

INCORPORATION OF THE MEDICAL CIRCULAR AND MEDICAL PRESS.

NOTICE TO OUR SUBSCRIBERS.—It is with the greatest satisfaction we announce to our Subscribers and Supporters that on and after the termination of the present Volume, the MEDICAL CIRCULAR will add immensely to its power and influence by becoming incorporated with the 'Medical Press,' a Journal which is known to enjoy a great amount of Professional favour and a circulation equal to, if not exceeding, that of the MEDICAL CIRCULAR. The advantages to all parties, whether proprietors, editors, contributors, or advertisers, from such an incorporation will be at once manifest, and when we assure our readers that arrangements are making to extend the circulation to the Colonies, to the United States, and wherever the English language is spoken, we may confidently claim for THE MEDICAL PRESS AND CIRCULAR in periodical literature, a rank equal to that of its most favoured contemporaries. No pains will be spared to make the United Journals worthy of the general support of the Profession, and there will be no hesitation at expense in its production.

We venture to claim for THE MEDICAL PRESS AND CIRCULAR the following advantages which, we hope, will recommend it to a large support from the Medical Profession:—

SPECIAL ISSUES FOR ENGLAND, SCOTLAND, AND IRELAND.

Enjoying the advantage of a triple connexion, and being conducted by a separate Editorial Staff in each of the three divisions of the United Kingdom, it must possess facilities for the acquirement of information which no other periodical conducted by a single local staff can have, while at the same time the strictest caution is exercised to prevent the affairs or interests of any one class in the Profession from predominating in its columns. The purely Medical, Surgical, and Scientific portion of the Journal will be the joint contribution of the Schools of Medicine in London, Dublin, and Edinburgh, each equal to the other in talent and originality, while the Critical and Editorial Department will furnish material at once comprehensive and specially adapted to the requirements of each country.

LOW RATES OF SUBSCRIPTION.

While inferior to none in influence and merit, THE MEDICAL PRESS AND CIRCULAR will be the cheapest weekly Medical Periodical in the United Kingdom, to attain which qualification the Subscription rate of THE MEDICAL PRESS has been considerably reduced. The Subscription will be 17s. 6d. per annum, for Unstamped Copies, and 1*l.* 1s. 8d. free by Post; this latter rate being recommended, as it ensures greater regularity and rapidity of transmission. It is hoped that no Medical Man who desires to keep pace with the rapid march of Medical Science, will hesitate about the expenditure of a sum which would be amply repaid by the acquirement of a single fact of value in the practice of the Profession.

DAY OF PUBLICATION.

THE MEDICAL PRESS AND CIRCULAR courts no competition with other Medical Journals fully entitled to as much confidence as itself can be. It will, therefore, be published on Wednesday—a period intervening between the day of issue of other Medical Journals—in the belief that it will be read alike by every Medical Man whose position enables him to subscribe to other Periodicals, and by the Practitioner, to whom a reliable Medical Record at an economic rate is a matter of importance.

THE MEDICAL CIRCULAR.

WEDNESDAY, DECEMBER 20, 1865.

THE PROGRESS OF CHOLERA.

The subject of cholera, although a gloomy one, continually forces itself upon the attention of the Profession, and we therefore make no apology for alluding to the long, able, and we might add, exhaustive discussion which took place on this fertile theme a short time since at the Harveian Society, and which we fully reported in our columns of last week. On the occasion to which we refer, the speakers detailed for the most part the records of their own personal experience; no dogmatic views were asserted; no infallible remedies were announced; and even where differences of opinion existed, the grounds on which the differences existed were fully developed and explained. The contagionists and the non-contagionists had each many cogent arguments and facts to adduce in favour of their own views; and on the subject of treatment, while all spoke with reserve, none proposed any plan which could be considered altogether inconsistent with the nature of the malady they desired to combat.

Dr. Tilbury Fox, who opened the discussion by reading a paper on the "Cholera in Egypt," is entitled to great credit for the luminous manner in which he expressed his own conclusions as to the origin, nature, and progress of the disease, as observed by himself in a recent visit to Alexandria, Cairo, Jerusalem, Damascus, and other eastern localities where cholera has lately prevailed. He fixes the original seat of the disease in India, which he considers the nursery of cholera, and he believes that during the late epidemic visitation in the East, it was brought from India to Mecca by the poor Indian pilgrims who arrived half-starved, with attacks of diarrhœa, at the port of Jeddah; and arguing from this circumstance, he urges the necessity of the strictest supervision, by way of quarantine, being exercised at this and other ports, in case of the outbreak of any future epidemic. Dr. Fox is a strong believer in the contagiousness of cholera, and he thinks that the way in which the epidemic might have been strangled at its birth, was by placing under quarantine all vessels coming from India and arriving at Jeddah. In his opinion, England has a great responsibility in connexion with the propagation of cholera, because our ships left India in great numbers and thus brought the disease to Africa and Europe. Dr. Fox, however, was not very successful in explaining the occcurrence of sporadic cases at a distance from a focus of infection, but supposed that currents of air or a moist cloud might in some instances convey the seeds of disease. In reference to a subject which has often been discussed, Dr. Fox believes that diarrhœa is not by any means necessarily an early stage of cholera, and he goes so far as to assert that collapse is independent of the diarrhœa in true cholera. On the subject of treatment he throws very little light, but he protests against the indiscriminate use of ice to the spine, and thinks that salines are useless. He introduces, however, what we believe is a novelty in treatment, namely, the administration of strychnia, one-twelfth of a grain being, he tells us, sometimes given with good effect, or even one-fourth of a grain in severe cases. This alkaloid has probably been recommended from its known power of stimulating the spinal cord, and thus arousing the energies of the system in the stage of collapse; but we cannot believe in the propriety of using so powerful and dangerous a remedy until very strong reasons are advanced in its favour by the advocates of the plan.

Dr. Headlam Greenhow, who has had peculiar opportunities of observing the progress of cholera during the epidemics of 1849 and 1854 in this country, declared that no real instance of contagion had ever come under his notice, and we think that this gentleman's evidence on this point is entitled to very great respect. In reference to the views of those who advocate the endemic or local origin of cholera from foul air or vitiated water, and in answer the question why, if such be the causes of cholera, the disease does not prevail every year, he observes that another factor is needed in addition to the local causes, and this is a peculiar meteorological condition which has been found to prevail during and before every epidemic of cholera. The barometer has been high, the atmosphere remarkably still, the temperature above the average, and the rainfall insufficient. He considered quarantine regulations as useless, and he thought that the attention of the Medical Profession and of the public generally should rather be directed to the removal of local conditions, which appeared, under every existing theory, to be necessary to the spread of the disease. We think it very difficult, especially for those who watched the epidemics in 1849 and 1854, to doubt the cogency of Dr. Greenhow's remarks.

We ourselves, however, desire to offer no dogmatic opinion upon the disputed questions connected with the origin or progress of cholera, but as all the authorities agree upon certain points, we would urge these upon general notice. The points of agreement, then, among contagionists and non-contagionists, are that poverty and misery, bad ventilation, overcrowding, and dirt, are, if not the originators of the cholera epidemic, among its most favoured allies, and where these are absent, cholera obtains but few victims. The recent epidemic on the continent of Europe and in the East, bears abundant evidence to the truth of this view, for precisely in those localities where the greatest misery prevails, and the greatest neglect of sanitary measures is allowed, there does the cholera prevail most extensively and commits the greatest ravages. It is not asserted that those who are higher in the social scale, and enjoy a greater degree of comfort, are exempted altogether from the scourge, for persons who live in ease and are surrounded by luxuries, are often swept into the general vortex, while the Medical attendants of the sick often fall victims to their own zeal and courage.

Still the fact remains that among the poor does the greatest mortality prevail during a cholera epidemic, and

with the sad prospects before us this winter of the high price of butcher's meat and of coals, the condition of our lower classes ought to engage the attention of the wealthier portion of the community. It is difficult, if not impossible, for Government to interfere directly in such a matter, but it is the bounden duty of all local authorities to relieve, as far as may be, the distress which they see around them. At the approaching festive season, when the hearts of mankind are warmed to sympathy by the remembrance of the birth of the Great Teacher, who went about doing good, let everyone as he meets his own family circle, *remember the poor*. "He that giveth to the poor lendeth to the Lord," but if a more selfish plea be needed for the exercise of more than usual charity at the present time, it will be found in the reflexion that by providing food, fuel, and raiment for the poor, not only may the impending pestilence be divested of half its terrors, but it may be averted altogether. The cholera poison, whatever be its nature, must have a soil for its development, and this soil is always prepared wherever poverty and destitution, with their concomitant miseries, most abound.

DR. RICHARDSON ON THE POISONS WHICH PRODUCE EPIDEMIC DISEASE.

At the meeting of the Metropolitan Association of Medical Officers of Health, last Saturday evening, Dr. Richardson opened an interesting discussion by reading a paper on the poisons which produce epidemic disease. Instead of describing, as might have been anticipated from the title of his paper, the various malarious influences existing in our streets and dwellings, and giving rise to our well-known fevers and other epidemics, he entered into a very ingenious argument to prove that the theory or hypothesis of the zymotic nature of those affections was erroneous, and that they really arose from the communication of morbid secretions from one person to another, and that, in fact, morbid animal secretions were the poisons causing epidemic disease. The starting-polnt of his own hypothesis was a case of pyæmia, in which he had submitted the purulent matter to chemical analysis, and had obtained it in a separate state by chemical re-agents. From this circumstance he concludes that the rest of the animal poisons have a definite composition, that they are generated by a morbid condition of the albuminous portion of the blood, and that this matter, entering into other bodies, facts like the ordinary poisons, such as morphia, veratria, or strychnia. He believes that these animal poisons are of the nature of alkaloids, that they are combined in the body with peculiar acids, and that they exert a poisonous influence by chemical agency on the blood of persons into whose bodies they are introduced. This view of the nature of epidemic poisons has been worked out by Dr. Richardson with his well-known ability and ingenuity, and if it should turn out that it is supported by a sufficient number of facts, it will modify very considerably our present opinions upon many diseased states. But there are many difficulties in the way of its reception, not because the zymotic hypothesis is altogether satisfactory, but because it is the best that has yet been offered. Zymosis, which is the same word as the Latin *fermentatio*, implies the disturbance caused in some compound body by the introduction of something, which both decomposes the surrounding fluid, and multiplies itself indefinitely, as is seen in the introduction of a portion of yeast into a beer-vat. Although it cannot be said that the phenomena of an attack of typhus or cholera are exactly analogous to those of fermentation, yet there is a certain degree of resemblance in the two processes, quite sufficient to justify the use of the word *zymotic*, and although the miasm of contagion has not yet been isolated, it is only fair to conclude that such a body exists. But Dr. Richardson declares that in one case he has actually isolated the contagious matter, and he infers, as we have stated, that it acts upon the blood like an ordinary poison, and not as a catalytic agent, in the sense in which that term is generally understood. But we shall hereafter notice more fully the facts on which Dr. Richardson endeavours to establish his proposition.

THE CATTLE DISEASE.

This malady, in spite of all that has been done and attempted, has attained proportions much beyond what might have been reasonably anticipated. Its progress has not been checked, but, on the contrary it has entered districts hitherto free from its fatal influence, and, according to carefully collected returns, there are only three counties in England where it has not appeared with more or less severity, and eight in Scotland ; while in Wales there are only two counties wherein it has broken out. The Privy Council returns, however, do not profess to give the total number of cases which occurred in Great Britain, but only those which have been ascertained from the official information received from inspectors, or by the local authorities. According to these returns the total number of reported cases since the first appearance of the plague amounted up to 39,714, of which number 10,787 were killed, 19,936 died, 2,900 only recovered, while 6,082 still remained in a suffering state. Middlesex, including the metropolis, Yorkshire, eastern counties, south midland counties, south eastern counties, and north western counties appear to have been the principal seats of the disease in England. Scotland has also suffered severely, having had 12,424 of her beasts attacked by the disease. Of these 1,999 were killed, 6,603 died, 1,258 recovered, and 2,564 are still suffering. It is calculated that of the total number of cattle in farms, in sheds, and other places where the disease has been officially reported to exist in Great Britain, 44·123 per cent. have been attacked. In the metropolitan districts there has been the greatest loss, the number attacked being 61·238 per cent. of the whole existing number. These figures measure, with unerring certainty, the extent of the disease.

The Government, through the medium of the Privy Council, have given proof that they have not underrated the gravity of the disease. They have taken every step they could to obtain information upon the subject, both in this country and on the Continent ; and they have ever shown themselves ready to listen to all complaints and to entertain all suggestions having for their object both prevention and cure. They have availed themselves of the powers placed in their hands by law, within certain limits, and have promptly endowed the local authorities with such powers as they required to deal with the disease. All that has been done, had to be done under great disadvantages, because the malady to be encountered was unexpected as well as new.

The Royal Agricultural Society, have exerted themselves to suggest means to subdue the malady. On Thursday week a deputation from that body waited on Earl Granville and Sir George Grey with a set of resolutions embodying the views of the council on the subject, and submitted them to the Government. The society recommended very sweeping measures, the most effectual of which, they think, would be to stop all fairs and markets. If this cannot be done, they would brand and kill any cattle, sheep or pigs offered for sale in a market or fair, or near any town, with the object, apparently, of preventing any sales except for immediate consumption. They desire that no cattle, sheep, or pigs should be offered for sale more than once, except on the premises of the owner, and they would brand and kill all cattle offered for sale in any other place whatever, provided they had not been in such place for three weeks. They would have all foreign animals slaughtered at the port of disembarkation, but, if that cannot be done, then they propose that these animals should be inspected, certified, branded, and sent in to be killed at specific places. They would prohibit the transfer of animals from any farm or place where the disease has appeared within two months. They wish the Government io supersede the local authorities in enforcing these regulations, and, finally, they ask the Government to make extensive experiments, with the view of discovering the real nature of the disease, and testing the various methods of prevention and cure.

These recommendations, however, were deemed by the Government of a far too sweeping tenor and character, and Sir George Grey remarked to the deputation that, in most of the places where the disease has appeared, fairs and markets have been discontinued, and he thought it best to leave the local authorities to deal with the cases as they deemed fit. But to this it was answered that the local authorities were not sufficiently prompt, and Lord Washingham pointed out that in some places the authorities have a pecuniary interest in keeping the markets open. Where markets are kept open for motives of that kind it might seem right to interfere, but it may be fairly questioned whether that allegation would afford ground for making one iron rule for the whole country.

On Thursday morning a meeting was held at St. James's Hall of the representatives of the local agricultural societies and farmers' clubs of the United Kingdom. A large number of gentlemen attended, and on the motion of Mr. Tollemache, M.P., Lord Combermere was voted into the chair. A letter was read from the Duke of Rutland expressing an opinion that the Government would be much to blame if they did not take more stringent measures to prevent the removal of cattle, and advocating the establishment of a National Insurance Society with a Government guarantee.

Several speeches were made and resolutions moved, and eventually a deputation was appointed to wait on Sir George Grey.

The deputation appointed at the meeting had an interview after the meeting with the Home Secretary at his official residence, Downing street, with a view of laying before him the views there expressed. The deputation consisted of Lord Combermere, Lord Hill, Lord Leigh, Sir J. Tyrell, Hon. C. H. Cust, Colonel North, Mr. C. S. Read, M.P., and deputations from upwards of thirty counties and 100 local agricultural societies. The deputation was introduced by Lord Combermere, who, as chairman of the public meeting previously held, explained its objects, and read the resolutions which had been unanimously adopted by the meeting over which he had presided.

The resolutions advocated the entire and complete suppression of the transit of cattle from place to place for a limited period, unless the transit could be regulated in a uniform manner by Government.

Sir George Grey considered that the present Orders in Council were sufficiently stringent in their character, and from all he could learn he was of opinion that, if properly acted upon by the local authorities, they would be sufficient to meet the exigencies of the case and stay the evil. The disease was unknown in Ireland and Wales, except in one county, that of Denbigh.

Lord Hill had found, as Lord Lieutenant of a county, the action of his magistrates very unsatisfactory. The local authorities were anything but unanimous, and there were almost insuperable difficulties in the way of inducing them to take vigorous action.

Sir John Tyrell could inform Sir G. Grey that the Orders in Council, as executed by the local authorities amounted in effect to a solemn and pompous farce.

A long and desultory discussion ensued, during which several speakers addressed the Home Secretary, one remarking that the reason why the cattle disease had not infected Ireland was because the importation of cattle had been stopped from the first. Another speaker corrected Sir G. Grey's statements respecting Wales, assuring the right hon. gentleman that within the past fortnight the disease had committed fearful ravages in Flintshire. Other speakers pointed out to the Home Secretary, from practical experience, how the Orders in Council were avoided by fairs or markets for the sale of cattle being held and large numbers of cattle being collected together outside the limits of the districts where the Orders had been put into force.

Sir G. Grey asked the gentlemen what course they were prepared to recommend, and how far they would be prepared to recommend or support restrictive measures.

Mr. Clay, on behalf of the deputation from the Farmers' Club of Wakefield, stated that so far as he had been able to gather from opinions expressed in his own locality, and that of the public meeting held that morning, which represented thirty counties—a very large portion of the agricultural interest—the farmers were prepared to submit, as the least of two evils, to the total stoppage of the transit of cattle from one place to another, even upon their own farms, should such transit involve the passage upon the highways, rather than incur the risk of spreading the disease by continuing the present tinkering Orders.

Sir G. Grey.—What! Are you prepared to stop entirely the transit of cattle for breeding purposes?

At this there was some little disagreement. One gentleman considered it impracticable to stop the removal of cattle upon a man's own farm.

Sir G. Grey inquired of Mr. Read, M.P., whether, as he now identified himself with the deputation, his opinions had changed with respect to restrictive measures, as he had been in the minority upon the Cattle Plague Commission.

Mr. Read replied that his opinions remained unchanged. The resolution submitted only asked for a total suppression of the transit of cattle if the Government considered it practicable. Circumstances had changed. What was impracticable some months since might be both practicable and expedient now.

After some further conversation,

Sir George Grey remarked that he should be most happy to lay the views of the deputation before the Privy Council, with the resolutions which had been submitted to him. He would do it in this form—that a majority of the deputation was in favour of the opinion that a total suppression of the removal of stock, even upon a man's own farm, was expedient for a limited period.

Here Lord Hill interposed, and said that was the unanimous opinion of the deputation, and begged leave to put it to the vote. He invited a show of hands upon the question, and at his request about fifty hands were held up in favour, and only three in the negative.

The deputation then thanked Sir G. Grey and withdrew.

The following memorial has been presented to the Lords of Her Majesty's Most Honourable Privy Council:—

"We, the undersigned occupiers of land near Lincoln, beg respectfully to state to your Lordships our conviction that in nearly all cases of rinderpest the outbreak of the disease has been occasioned by contact with affected animals, and that the only preventive against its universal spread is the isolation of cattle as far as can be carried out.

"Strongly entertaining this view, we beg to submit to your Lordships that no cattle should be allowed to be removed from any farm or market except for the purpose of immediate slaughter; that the driver of cattle so removed

should be furnished by the owner with a ticket signed by him, and stating the name and residence of the butcher to whom they have been sold; that the police should be empowered and required to inspect such ticket in all cases when they find cattle driven along any highway.

"That in all cases where a ticket containing the required particulars cannot be produced, cattle should be returned to the owner, who should be liable to a penalty.

"That in the case of cattle bought from a farmer, or in any fat stock market still remaining open, such cattle should be so marked or branded that they may afterwards be known and that the owner be liable to a fine of 20*l.* if they be found alive after forty-eight hours from the time of their having been exposed for sale, or from the time of their having been received into the possession of any butcher.

"That the manure from yards or land on which affected animals have been shall not be placed within 200 yards from any highway.

"Your memorialists, as practical men, are well aware of the inconvenience attending such a course of procedure, but having seen the spread of contagion by the unrestrained removal of cattle from markets at York and Beverley, and attributing the absence of rinderpest in this immediate locality to the fact of the Lincoln market having been effectually closed, and to the exertions of the police in seeing that every head of cattle brought to Lincoln has either been slaughtered or directly returned to the owner, we, your memorialists, therefore pray that your Lordships will take these matters into your earnest consideration, and make such orders as you may think necessary to prevent the further spread of this contagious disease.

"Signed by the memorialists."

MEDICAL SOCIETIES.

(Continued from page 439.)

the sheath of these tendons should never be opened, but Mr. Paget had shown that cases in which they had been thus interfered with, did well.

Mr. BALMANNO SQUIREL showed a

COLOURED PHOTOGRAPH OF KELOID.

In this instance the tumour had formed in a scar left by syphilitic rupia. Mr. Squire entered into a description of the difference between spontaneous keloid and keloid of cicatrices.

Mr. NUNN showed a cast from a case of

UNUSUAL INJURY OF THE ELBOW-JOINT.

The ulna had been dislocated on to the internal condyle. The patient was examined fourteen days after the accident, but then it was impossible to reduce the displacement. Mr. Nunn remarked on the extreme rarity of the accident. Mr. Arnott, who saw the case with Mr. Nunn, had never before seen such an accident. The injury did not seem to impede the action of the joint. Perhaps there was some fracture of the trochlea.

Mr. BARWELL showed a specimen from a case of

STRANGULATED HERNIA IN A TUMOUR OF THE INGUINAL CANAL.

The patient had been under the care of Mr. Chaldecott, of Dorking, for strangulated hernia. He had constipation and stercoraceous vomiting, and yet he refused an operation until he was moribund. At the operation it was found that on one side of the ring was a tumour. The gut was all apparently returned, but the symptoms continued. At the autopsy, the stomach was found to be strangulated though the ring into the tumour. Mr. Barwell then related a case of umbilical hernia, in which there was a similar state of thiugs.

Mr. HOLMES remarked that the specimen was a very rare one, and requested that a report should be made.

Mr. BARWELL, Mr. HULKE, and Mr. HOLMES, were appointed to report on it.

OBSTETRICAL SOCIETY OF LONDON.

DR. BARNES, PRESIDENT.

WEDNESDAY, NOVEMBER 1ST, 1865.

THE PRESIDENT announced that the Council had resolved to hold a *conversazione* in March next, for the purpose of exhibiting a full collection of instruments used in obstetric practice.

Dr. BARNES exhibited a monstrous Fœtus brought to him by Mr. Thane, of Canonbury. Also, a voluminous Fibroid Tumour, weighing 1 lb. 13 oz., which with the assistance of Dr. Hicks, he had successfully removed from the uterus of a lady a month ago.

Dr. RUSSELL, of St. Albans, laid before the Society the particulars of a case of Hydatiform Degeneration of the Ovum.

Dr. AVELING read a

CASE OF OVARIOTOMY IN WHICH THE PEDICLE WAS TIED AND RETURNED, AND THE LIGATURE REMOVED IN FORTY-EIGHT HOURS.

The operation was performed as follows:—As soon as the cyst was reached it was tapped, and the fluid (twenty-one pints) withdrawn. No adhesion existed, and the sac was withdrawn easily. The pedicle, which was short, and about four fingers in breadth, was transfixed by a needle carrying a double thread. The two ends of each ligature were then brought up on either side, and drawn through two wire coils five inches and a half long. Each coil had fitted upon its end a cross-bar; and around these cross-bars the ligatures were secured after they had been drawn sufficiently tight to compress the vessels. The pedicle, after it had been placed on the hook of Dr. Aveling's polyptrite and crushed through, was then returned *in situ*, and the wound closed with iron-wire sutures. The coil-clamps were removed in forty-eight hours; and the patient made a favourable recovery.

Mr. SPENCER WELLS said that no one method of dealing with the pedicle could be applicable in all cases of ovariotomy. A long pedicle was dealt with so successfully by the clamp that he desired no better method; but it was still doubtful what was the best mode of proceeding when the pedicle is short. The plan of leaving the ends of silk or twine ligatures hanging out through the wound was so unsuccessful, that the apparatus of Dr. Aveling would probably prove of great advantage in cases of short pedicle in weak patients.

Dr. MARION SIMS said that the clamp was a great improvement on the ligature. He thought Mr. Baker Brown's plan of severing the pedicle by the actual cautery promised great results. He viewed Dr. Aveling's method with favour. He always used a silver wire, and left it to be sacculated. He said the distal end of the severed pedicle did not slough where the wire was applied. The wire became imbedded and hidden in its tissues.

Mr. GEORGE ROPER read the particulars of a

DIFFICULT CASE OF LABOUR, IN WHICH THE CERVIX UTERI WAS HYPERTROPHIED AND UNEVOLUTED.

A. E——, aged thirty-seven, in labour with her eighth child, was found to have the cervix uteri elongated and enlarged, so as to fill the vagina. The os externum was sufficiently dilated to admit the hand, but the os internum was undilated. The occiput presented. Version having been tried and failed, and the funis being pulseless, the head was perforated, and after some difficulty the child was extracted. During extraction the cervix uteri protruded from the vulva, and the effects of pressure and distension on it could be well observed. The difficulty consisted, not in having a rigid os uteri to deal with, but the entire cervix had to be expanded, dilatation of the os internum constituting the chief difficulty. The author discussed the question whether craniotomy alone, or dismemberment and exvisceration of the fœtus, is the best for such a case.

Dr. J. MARION SIMS read a paper on

PROCIDENTIA UTERI.

He said that a procidentia was complete when the vagina was inverted and formed its outer covering—incomplete when the cervix only passed through the vulva; that a

broad pubic arch, divergent rami, a relaxed perineum and a retroversion, were essential to its production; that in some cases the infravaginal cervix was elongated, and came down first, but that in the majority of chronic cases a vagino-cystocele formed the first stage of procidentia. For the first he advocated amputation of the cervix, and said this was generally alone sufficient; but for the second he preferred to narrow the vagina. This idea, he said, originated with Marshall Hall; but he did not think the operation had ever succeeded till the introduction of metallic sutures. He then gave an account of the operation from the time he first performed it in 1857 till now, showing its gradual advancement to its present state of perfection. He illustrated the subject fully by diagrams. In 1857 he narrowed the anterior wall of the vagina by exsecting a large ellipsis of it, and then bringing the lateral borders together with silver sutures. Afterwards he simply denuded the surface of its epithelial membrane; then he simplified the operation by making a V-shaped scarification; and subsequently he made it trowel-shaped or triangular, the point being at the neck of the bladder, and the broad portion in juxtaposition with the cervix uteri. In all these methods, the object was to remove the systocele, and afford a support to the parts just at the anterior cul-de-sac. By diagrams he illustrated the method of operating, and claimed for it, when properly done, the greatest success. He did not pretend to institute a comparison between this and the perineal operation for the same trouble, but he had been driven to work out this plan in consequence of having often failed with the other. He only wished to add another resource to our means of curing such a disgusting infirmity, for we now had three methods: 1st, amputation; 2nd, the perineal operation; 3rd, the narrowing of the vagina, as advocated by him.

Mr. NUNN stated that he had on several occasions operated for prolapsus uteri after the plan recommended by Mr. Baker Brown. In most of the cases a partial rupture of the perineum had existed. In them the result of the operation was satisfactory on the whole. Where no rupture of the perineum existed, as in young women who had never borne children, Mr. Brown's operation failed. He also stated that he had himself adopted, and had also seen Mr. Brown on many occasions practise, a proceeding *somewhat* resembling that described by Dr. Sims—namely, the removal of a V-shaped portion of the mucous membrane of the vagina reaching from the fourchette to within an inch or so of the cervix, the difference being that this removal was made from the posterior instead of the anterior or vesicall wall of the vagina.

Mr. SPENCER WELLS said that the operation suggested by Dr. Marshall Hall had been performed many years ago in London. He (Mr. Wells) had seen two ladies upon whom it had been performed by the late Dr. Hemming, of Kentish town.

Mr. CHAMBERS regarded Dr. Sims' proposal as a valuable contribution to female surgery; but, in common with Mr. Baker Brown, he (Mr. Chambers) had for years past combined the two operations in cases requiring such a procedure, and he felt bound to say that the antrior operation, as performed by Mr. Brown was a very simple one when compared with Dr. Sims'.

Dr. WYNN WILLIAMS remarked that, as regards the success of the operation performed by Mr. Baker Brown, he had met with several cases, and he must say that the patients appeared to him to have been but little benefited by the operation. He recommended a pessary, which acts by making tense the mucous membrane reflected from the vagina to the uterus, the uterus being suspended between the blades of the pessary.

Dr. WILKINS, of William's town, Australia, stated that he had operated on two cases of procidentia uteri, following closely the method of Mr. Baker Brown as described in his book. Permanent success had followed the operation, even though one of the cases had been of twelve years' standing. Dr. Tracy, of Melbourne, had also operated on several cases, and he believed with similar results.

The PRESIDENT said he had himself performed Mr. Brown's operation several times. He had found prolapsus return in spite of the provision of a good perineum. Further, he had repeatedly seen the uterus return *in situ* notwithstanding large perineal luxation. It seemed to him that Mr. Brown's operation was performed in the wrong place. It had no effect in providing support where it was wanted—namely, anteriorly, at the connection of the cervix uteri with the base of the bladder. This object seemed to be perfectly accomplished by the admirably reasoned-out and ingenious operation of Dr. Sims.

Dr. SIMS, in reply, seid that no one method of operating could be applicable under all circumstances to all cases. If there was a lacerated perineum it was proper to restore it. If there was elongation of the infra-vaginal portion of the cervix, then the proper operation was amputation of the cervix, and this was probably all that was necessary in such cases. In the majority of cases of procidentia—in all those where a vagino-cystocele formed the first stage of descent—he was satisfied that the operation he had described—viz., that of narrowing the vagina by forming a longitudinal fold of its tissue on the anterior surface, reaching from the neck of the bladder to the neck of the womb, would be one of the safest, simplest, and best.

ABSTRACT OF A PAPER ENTITLED "NEW REMARKS ON THE PREMONITORY STAGE OF CHOLERA." BY M. GUERIN.

Since his first memoir on the subject, M. Guérin has ascertained the fact that not only individual cases, but epidemics in general, are preceded for several months by a kind of premonitory diarrhœa. This view is now fully confirmed by our recent experience. Diarrhœa gives notice of the imminence of cholera in individuals, and prevails extensively in the districts threatened with a visitation of the scourge; its presence is observable in localities adjacent to those in which cholera has already made its appearance, and in the towns and villages invaded by that disease, and often may be noticed in entire quarters, streets, or sides of streets; while cholera decimates the population in other quarters, streets, or sides of streets in the same city.

These collateral facts are assuredly sufficient, in M. Guérin's opinion, to establish the close and reciprocal connection existing between premonitory diarrhœa and cholera, and to show that in persons labouring under confirmed cholera, as well as in those who are merely attacked by premonitory diarrhœa, and also in the localities in which the disease has not yet assumed its most aggravated form; in short, that wherever diarrhœa prevails during an epidemic of the Asiatic affection, the seeds of cholera are present, and only await a favourable opportunity to acquire their full development.

If any doubt remained on this point, it would, according to the learned editor of the 'Gazette Médicale,' be dispelled by the remark that the diarrhœa consequent on cholera poison, whether premonitory or characteristic of the confirmed disease, scarcely ever exists alone, but is almost invariably accompanied by nervous disturbances, such as singing in the ears, giddiness, slight cramps, a sensation of chill, cold perspiration, nausea and marked general debility. These symptoms are obviously but the attenuated outline of true cholera, impart to the coincident diarrhœa suggestive characters, and demonstrate the common origin both of the diarrhœa and of confirmed cholera.

What was formerly called the *epidemic constitution*, and was considered to be a peculiar state of the atmosphere, and of the system of man and animals, induced by undefined and latent causes is, therefore, for the author but the partially developed produce of those causes which will subsequently generate disease in its complete form.

From these data, M. Guérin derives Medical and administrative inferences.

The former the author has expounded in his earlier publications on the subject; in these he expatiated on the practical benefits derivable from a knowledge of the existence of a premonitory stage in cholera, during which the symptoms are amenable to treatment. If diarrhœa is controlled, cholera need never be apprehended; a fact now fully demonstrated,

but which should be further promulgated. M. Guérin observes, with regret, that the researches of investigators seem rather to be directed towards the discovery of some specific sufficiently powerful to resuscitate the dead, than towards the study of the period at which the impending evil may yet be averted. But what science has but limited means of accomplishing can easily by realised by the executive. In this respect, a thorough conviction of the existence of a prodromic stage in cholera, marked by painless diarrhœa might lead to the adoption of measures of paramount importance to the public.

Thus in England, a country in which practical suggestions are certain to find an echo, the public has received the benefit of the natural inferences from the facts it is my purpose to establish. Whilst in France, the very name of the man who first demonstrated the existence of a premonitory diarrhœa in cholera, is forgotten, a complete system of sanitary measures has been organised in England for the twofold object of pointing out the possibility of arresting cholera in its mild stage, and of teaching what remedies are most appropriate at all periods.

A method of house to house visitation in the localities infected by cholera has been established, which has led to the discovery of the earliest signs of the disease in individuals who had not even a suspicion of its presence. This system applied in 1848 and 1849 in most of the localities invaded yielded results which exceeded the most sanguine anticipations.

In Scotland, at Dumfries, a city which numbers 10,000 souls, 250 persons had already died before the system came into operation; three days were employed in the necessary arrangements, and durings these three days the numbers attacked were successively thirty-seven, thirty, and twenty-three; the deaths were seven, five, six. During the following three days the number of fresh cases was eight, four, two, and the deaths, six, four, and five. Three days after, the epidemic had ceased.

At Glasgow, 13,139 cases of premonitory diarrhœa were placed under treatment, the rice-water dejection existing in 1,000 instances. In twenty-seven only did confirmed cholera ensue.

In London, in the course of three weeks, from the 1st to the 27th October, 1849, the visitors recorded 43,737 instances of diarrhœa, in 778 of which the rice-water appearances were present. Of this large number fifty-eight only passed into confirmed cholera.

In conclusion, in the fifteen principle towns of England in which the preventive system was more or less completely applied, 130,000 persons were placed under treatment, and 250 only became affected with fatal cholera, although 6,000 at least were threatened with the worst form of the disease.

At Munich the same system was resorted to on M. Guérin's suggestion, and under the supervision of Dr. Hartmann, the king's private physician, and the city escaped almost altogether from the effects of the scourge.

The French executive has taken note of these results, and has instructed the Board of Hygiene to inquire into the measures adopted in England, and to report thereon. Dr. Mélier was appointed to carry on the investigations and has pursued his researches with the utmost diligence; the government is now, therefore, in possession of a complete system of measures which, if so inclined, it might put into operation under present circumstances. — 'Journal of Practical Medicine and Surgery' for November.

TREATMENT OF FRACTURE OF THE INFERIOR EXTREMITY OF THE RADIUS.

This kind of injury is of such frequent occurrence in winter, that it may not be inexpedient to reproduce a brief abstract of M. Jarjavay's practical remarks on the subject.

Few fractures, said the Professor, have attracted so much attention as that of the inferior extremity of the radius. Excellent memoirs and exhaustive papers have been devoted to the mechanism, morbid anatomy, symptoms, prognosis, and treatment of this injury, and the most eminent surgeons have closely inquired into these various points. Indeed, we may say that almost too much attention has been bestowed on the choice of the most appropriate apparatus, and M. Velpeau has shown that the greater number of the dressings applied since the days of Dupuytren have been more injurious than beneficial. Hence, as M. Lecomte sagaciously remarks, has arisen a tendency to simplify the modes of delegation. It is true that a few years since surgeons have used systems of contention of too complicated a nature, but we seem now to have reached an opposite extreme, and some authors have ventured to recommend mere position as an adequate substitute for reduction and bandaging. MM. Hervez de Chegoin, and Robert, for instance, have stated when the forearm rests on a solid horizontal surface, the displacement of the inferior fragment may be reduced by the mere weight of the hand.

A wise practitioner should preserve a just medium between these extreme views, and while desirous of obviating deformity and obtaining a prompt restoration of the functions of the limb, may, after complete and immediate reduction of the fragments, materially shorten the usual length of the treatment.

Many procedures have been recommended for the purpose of effecting reduction. M. Jarjavay enumerated them all, and after glancing at their respective merits, described the plan he has himself adopted, and of which we have on several occasions witnessed the successful application.

The following is the rationale of the procedure:—

In order that the whole of the power applied should be efficaciously used for reduction, it should exclusively bear on the two fragments. The direction of the force must in addition be such that the motion imparted to the fragments be exactly the reverse of that given to them by the force which occasioned the fracture—*i.e.*, that admitting the carpal extremity of the lower fragment to have described backward an arc, the radius of which has its centre in the fracture, the same extremity must, in order to be restored to its natural position, describe an inverse arc of the same extent, but forward. The fracture having bent back the extremity of the bone, its reduction requires the fragment to be bent forward. M. Jarjavay proceeds on this principle as follows:—

The patient's forearm is placed in a prone attitude, with the hand hanging down. An assistant secures the elbow, while the operator, joining both his hands and crossing his fingers, grasps the wrist in such a manner that both forefingers support the lower extremity of the superior fragment, while with his crossed thumbs he presses over the posterior surface of the carpal fragment. The wrist is thus enclosed in a circle, the inferior part of which supports the upper fragment of the radius, while its upper half acts on the inferior fragment. The surgeons then perform with his clasped hands a movement of pronation, which forces back the superior fragment and brings forward the inferior one. M. Jarjavay uses considerable force to straighten the wrist in this manner, and has always found the procedure efficacious. The operation requires very little time, and the pain it induces is of short duration. If lateral deviation exists, the effort is directed in such a manner as to correct the displacement. Reduction may thus be most accurately effected, and the surgeon of hospital Beaujon is never deterred by the fear of producing pain or inflammation, contingences the gravity of which has been much exaggerated.

If the reduction thus obtained was not liable to be easily disturbed by the movements of the limb, all dressings would be equally injurious and unnecessary; but although it may in certain cases persist unchanged, the displacement frequently recurs—hence the necessity of securing the fragments, in all cases with an appropriate bandage.

In order to leave the joints of the hands and fingers at liberty, M. Jarjavay applies, from the elbow to the lowest part of the radius, two splints somewhat narrower than the forearm.

One of these is laid along the back and the other along the front of the limb, from which they are separated by a soft pad destined to protect the integument from the effects of pressure. The splints are secured at their upper and

lower extremities with a strip of adhesive plaster, the interval between them remaining uncovered. This apparatus is analogous to that used by M. Malgaigne, with this difference, that the hand is left entirely free. The carpal fragment is secured in a proper position by the dorsal splint, and for a few days the arm is worn in a sling, after which the patient is permitted to use the hand as if no dressing had been applied. This system of bandaging prevents the stiffness of the wrist consequent on the use of a more complicated apparatus involving the hand, while it affords all desirable security against displacement.

The period at which this dressing may be safely removed, and the time required for consolidation of the fracture, must now be considered.

From his experience of these injuries, both at hospital Saint-Antoine and at Beaujon, M. Jarjavay infers that in subjects under fifty years fracture of the inferior extremity of the radius is consolidated between the twelfth and the sixteenth day after the occurrence of the accident, and that the dressings may therefore be safely dispensed with after the sixteenth day.

In his private practice, M. Jarjavay does not even delay so long the removal of the apparatus. He conceives that on the fourth or fifth day, and *á fortiori* on the seventh, eighth, or ninth after fracture of the lower extremity of the radius, the surgeon is justified in dispensing with the splints, and in merely prescribing the use of a sling, and some caution in the movements of the limb. In addition, the dressing may always be easily reapplied, if displacement or undue mobility of the fragments is observed. If, on the contrary, no indication arises pointing to the necessity of a reapplication of the apparatus, the movements of the wrist and hand are restored with much greater speed, an advantage which all practitioners will fully appreciate.—'Journal of Practical Medicine and Surgery' for November.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on the 7th inst.:—John Davies, Wrexham; Henry Denne, Sandwich, Kent; John Prince, Staines; Reginald Palgrave Simpson, Torrington street; Alexander Tyndall M'Ivor, Falsgrave, Scarborough.

The following gentlemen also on the same day passed their first examination:—Robert Anderson, St. George's Hospital; Edgcumbe Cornish, University College; Alfred Courtnay B. Melhado, St. Bartholomew's Hospital; Edward Matthew Owens, Guy's Hospital; Edmund Cuthbert Ring, St. George's Hospital; Samuel Hignett Smith, King's College; William Edwin Williams, St. Bartholomew's Hospital.

CHARTER HOUSE.—We are happy to observe that Dr. Robert Fowler is a candidate for the vacancy created by the retirement of Mr. Miles. That gentleman is well and favourably known to the Profession by his very useful Medical Lexicon, a work displaying sound acquirements and great industry. His professional qualifications also are of the most sterling kind.—'Lancet.'

MR. WALTER RIVINGTON, F.R.C.S. Eng., &c., has just been presented by several students at the London Hospital with a handsome clock, "in grateful appreciation and remembrance of his services as Demonstrator of Anatomy during the winter session of 1864-5."

ANDERSONIAN MEDICAL SOCIETY, GLASGOW.—The following gentlemen have been elected office-bearers for 1865-6:—President: Dr. J. G. Wilson. Vice-President: Mr. Samuel Woodcock. Secretaries: Messrs. W. Dove Macfarlane and Robert Colquhoun. Treasurer: Mr. W. Easby. Librarians: Messrs. A. C. Moffat and J. H. Hill. Auditors: Messrs. James Robinson and J. T. D. Hughes.

IN MEMORIAM.—The professional associates of the late Dr. Bickersteth have gracefully paid their tribute to his memory by placing a tablet in the vestibule of Somerset Hospital, commemorative of his distinguished talents and eminence as a physician. Dr. Bickersteth's celebrity was not confined to the Colony, and we believe that thousands, in all parts of the world, who benefited by his counsel will endorse the words in the inscription, that "in his death Medical science and the public sustained a grievous loss." The tablet is of the purest marble, and bears the following inscription:—

In Memoriam
Henrici Bickersteth, M.D., F.R.C.S.,
Chirurgi Nosocomii Somerset
hunc lapidem
Socii illius Medici statuunt,
famam ejus celebrem,
dotesque insignes, admirantes
et collaudantes.

Mors ejus et Medicæ
arti et populo, magno
damno fuit.

E vita excessit
die vi. Augusti, mdcccclxii.
Æt. 49.

NATURAL SCIENCE TRIPOS, CAMBRIDGE, 14TH DECEMBER, 1865.—*First Class.*—Goodman, Pelerhouse; Hartree, Trinity; Dickson, St. John's.—*Second Class.*—Bennett, Emmanuel; Doughty, Downing; Danford, Trinity; Ramsbotham, Caius; Ward, Trinity; Neville, Magdalen.—*Third Class.*—Josswill, Caius; Lawes, Trinity.

THE RIBERI PRIZE.—Although more than sixty memoirs and works published during 1862-64 competed for the first, Riberi prize, the committee of the Turin Academy of Medicine has come to the decision that no one of them was of sufficient value and importance to call for its award. The seven authors whose works approach nearest the desired goal are arranged in order of merit as follows:—1. Polli, of Milan. 2. Desormeaux, of Paris, and Sperino, of Turin, *ex æquo*. 3. Simpson of Edinburgh. 4. Borelli and Cortese of Turin, and Marey, of Paris, *ex æquo*.

THE CHOERA IN PARIS.—The total number of deaths officially returned from October 1 to December 3 inclusive amounts to 6,011 Of these 4,602 occurred in October, 1,365 in November, and 44 in December. Of the 6,011 deaths 3,845 occurred in prisons and Hospitals, and 1,835 *à domicile*—The whereabouts of 331 not being stated.—'Gaz. Hebdom.,' Dec. 8.

RINDERPEST IN THE FRENCH ZOOLOGICAL GARDENS.—The 'Echo Agricole' states that the cattle plague is spreading among the animals in the Zoological Gradens of the Bois de Boulogne. It has attacked the goats, four of which were killed on Tuesday, making eighteen deaths among the animals since the arrival of some gazelles from London. Fortunately, the disease has not been observed outside that establishment, and the greatest precautions are taken to prevent it from spreading. All animals suspected of being infected are immediately killed.—'Times, Dec. 2.

DECLINE OF CHOLERA IN ITALY.—(From the 'Times'' Correspondent).—Florence, December 11.—The cholera seems dying out in Italy, and the daily bulletins from Naples and elsewhere record but few cases. The doctors are apprehensive of a fresh outbreak in spring, but the respite is at any rate agreeable, and it is to be hoped that advantage will be taken of it to adopt measures of cleanliness and other sanitary precautions, greatly needed in most parts of Italy. A Nice journal lately informed its readers that the cholera had appeared in Florence and daily carried off numerous victims, and that the foreigners who found themselves here had hastened in great numbers to quit the infected city. The 'Official Gazette,' of the 9th instant, denounced the above statement as a mere fiction, and declared the sanitary state of this capital to be in all respects excellent, and that there were no grounds for even suspicion of the existence of cholera. The object of the invention is not difficult to divine. Nice would gladly profit by the exceptional circumstances that have deterred so many foreign visitors from proceeding to Rome and to Naples. Cholera and quarantine have kept numbers back when actually on their way to one or the other of those cities, and with such travellers Florence seems to have been the favourite refuge. Doubtless the Nizzian hotel and lodging-house keepers view the influx to the new capital with jealous eyes, and really Florence might well spare them a portion of its unusually large floating population. Every corner is crowded, and has been for some weeks past.

CHEWING TOBACCO.—Mr. Hereford, Manchester city coroner, held an inquest on Thursday as to the death of John O'Neill, the son of a labourer, who lives in Gun street, Ancoats. The deceased, although only twelve years of age, had been employed in the manufacture of tobacco for three years. He was latterly in the service of Messrs. Brook and Waterworth, tobacco manufacturers, Swan street; but about three weeks ago, after experiencing the failure of his appetite, he complained of a lightness in his head, and ceased to work. He subsequently became very drowsy, and was seized with pains in his stomach. Medical aid was called in, but the lad died on Monday. It was suspected that his illness had been produced through the use of tobacco, and a post-mortem examination was made by Dr. Braddon, who found the mucous membrane of the stomach much inflamed and stained, and the heart pale and flabby. The brain was congested, and the coverings of the mouth and throat were stained brown. Dr. Braddon was of opinion that these appearances must have been produced by the chewing and swallowing of tobacco, and that the cause of death was the absorption of nicotine, the poisonous property of tobacco. The boy would not, he believed, have received any particular harm from his occupation. The deceased's mother said she had seen him smoke once, and his brother stated that he had seen him chew tobacco on one or two occasions. The foreman under whom deceased worked said that from the appearance of his mouth he suspected he chewed tobacco, and he also stated that he was in the habit of breaking the stalks with his teeth instead of cutting them. The jury returned a verdict of "Death from the absorption of nircotine."—'Manchester Guardian.'

A DRUGGIST FINED FOR SELLING ALMOND FLAVOUR.—A case of considerable interest was heard at the Borough Court at Bolton (December 2), in which Mr. Thomas Goodman, druggist, of Bradshawgate, was charged with having sold to a young woman "A certain quantity of virulent poison—to wit, half-an-ounce of almond flavour, such sale not being made in the presence of a witness," and defendant "not having at the time of such sale correctly entered in a book the names and addresses of such person and witness and the nature and quantity of the poison purchased, and the alleged purpose for which it was intended to be used, contrary to the Bolton Improvement Act, 1854." Mr. Hall, in opening the case, said the summons was laid under the 17th and 18th Victoria, otherwise the Bolton Improvement Act, 1854, the 138th section of which said that "If any chemist, druggist, or other person in Bolton sell any virulent poison to any person, except in the presenc of a witness, and do not, at the time of such sale, correctly enter into a book the names and addresses of each person and witness and the nature and quantity of the poison purchased, and the alleged purpose for which it is intended to be used, every person so offending shall for every such offence forfeit not exceeding five pounds: and the burden of proving that this enactment has been complied with shall rest on the person charged with such offence." In this case he should be able to show the Bench that on Friday night, the 24th ult., a young woman named Catherine Joyce went into the shop of Mr. Goodman, the defendant, and asked for some almond flavour, and that he gave her half-an-ounce. She afterwards drank the poison, and it destroyed her life; but Mr. Goodman was not held responsible in any way for the use to which she applied the liquid. It showed, however, the necessity there was that there should be such regulations as were described in the Act, in order to preserve life, and prevent persons from probably using a poisonous article for a purpose for which it was never intended. The poison in question, it was alleged, was sold without the necessary care being exercised, there being no witness there at the time, and no particulars asked from the young woman as to what her name was and where she lived, all of which particulars should be entered in a book. Mr. Hall then called witnesses to prove this case. Mr. Richardson for the defence, admitted the allegations which had been made against Mr. Goodman, and then proceeded to call the attention of the Bench to an extract from the "Manual of Medical Jurisprudence," in which Taylor said, "I cannot avoid remarking that we have here another instance of the disgraceful state of Medical police in this country, in the fact that a deadly poison like this is allowed to be sold by confectioners and others for the purpose of giving flavour to pastry and liqueurs." Mr. Hall: But read on, and you will find he says that almond flavour is a deadly poison, and gives several instances in which it has produced fatal results. Mr. Richardson: I have no doubt about it. But there was not a chemist and druggist in Bolton—and he now spoke in the presence of several—who would enter in their book particulars with respect to the sale of this article, because they did not believe it to be that virulent poison contemplated by the statute, such as prussic acid, or arsenic *per se*. On the contrary, almond flavour was used by confectioners generally—apparently innocently, but yet, if taken in excess it would be dangerous to life—it was used by them for the purpose of flavouring cakes. Still, Mr. Goodman, he was sure would in future, as would also most likely the whole of the respectable body of the chemists and druggists, feel it to be necessary to keep a record of the sale of this article. He deeply regretted that a fatality like this had happened; but the Bench must bear in mind that in no way had he been ancillary to the death of the young woman, because it had been shown that it was common for her master to send her to Mr. Griffin for almond flavour, and therefore if Mr. Goodman had even complied with the statute, yet if the deceased had been so minded, as was well said by the Coroner at the inquest, nothing could have prevented her taking the poison, so that there was no injury inflicted upon society so far as this case was concerned. Having met the case, then as they did, he thought the Bench would be of opinion that the infliction of a merely nominal penalty would meet the ends of justice. Alderman Haywood said he thought the inquiries indicated in the Act should be made in every case of a sale of poison, no matter how small was the quantity purchased, and that large quantities should only be sold to persons engaged in the confectionary business. Mr. Richardson said there were thirty-one chemists and druggists in the town, everyone of whom no doubt retailed the article in question. The Mayor, after a short consultation, said the Bench were unanimously of opinion that the case would be met by the infliction of merely a nominal fine, so as to act as a caution, and defendant would therefore be fined 5s. and costs. He thought the regulations of the Act should be carefully attended to in future, and that no poison, however small in quantity, should be sold without being entered according to the statute.

CRAMPS.—M. Guyon mentioned a plan which he had already described in 1852, and has again been found effective as a remedy for the cramps. His plan consists in straightening the contracted parts; the forearm for instance is firmly held in one hand, while with the other the fingers and hand are stretched out. In the same manner, when the spasmodic contraction occurs in the legs, the heel should be held in one hand, and the toes and foot straightened. The operation should be slowly performed, and the hand may or not be previously greased. The cessation of the cramps is immediate, and the procedure was adopted fifteen years ago with the best effects at Tunis, at the author's suggestion.—'Jour. of Practical Medicine and Surgery.'

OVARIAN EXCISION.—M. Ch. Labé then communicated a case of ovarian excision performed with success in Paris, and M. Verrier read a paper on the prognosis and treatment of pneumonia occurring during pregnancy. When pneumonia coincides with pregnancy, the period of gravidity is of no importance with regard to prognosis. Abortion before the seventh month is not more probable than premature delivery after that date. If abortion supervenes, it should be attributed not to the treatment, but to the progress of the pulmonary inflammation. Hence the author concludes that pneumonia, coincident with pregnancy, should be treated in the same manner as if no such complication were present, and that no consideration should interfere with the adoption of the necessary measures.

A KINDLY SUGGESTION.—The following letter to the editor of the 'Times' by one who signs only his initials, deserves the widest publicity:—Sir,—A letter which

appeared in the 'Times,' headed "A Kindly Suggestion," mentions that in Tothill street, Westminster, "a good dinner is provided for poor children of the Ragged School, and that the change in the physical appearance of the children has been most marked, far beyond what could have been believed before the trial was made, as can be testified by numerous visitors." Will you allow me to say that I can endorse the latter part of the above from the experience of the last two years, during which time a similar charity has been in operation, and has relieved more than 3,000 poor sick children? The Poor Sick Child's Dinner Table is at No. 2 Woburn buildings, near Upper Woburn place, St. Pancras. The dinner takes place every Monday and Thursday at 12 o'clock, and during the half-hour of dinner ladies from the neighbourhood are present to attend upon the children, and receive any visitors who may wish for information. These dinners are more particularly for sick and puny children, such as the doctors would say require food more than medicine. There are scores of such children in the immediate neighbourhood, and to whom a good dinner even once a week would be a great boon. The dinner tickets are sold to subscribers in small books of ten, and average 4d. each. The words "sick children, are interpreted widely, and include those who, from being half-starved, would actually become sick but for the relief thus afforded. We have had children so weak that they have had to be carried to the table, and the same children now walk in and take their places without assistance. You would be doing a good service to thousands of poor children if, by making this charity more known, you thus induced hospitals and dispensaries to send us children. I will undertake to supply any hospital or dispensary with tickets gratis for any number of children they may send, only hoping that the inhabitants of the district will enable me to continue the supply from year to year.

THE VENEREAL COMMISSION.—The Commander-in-Chief has, we hear, done the Venereal Commission the honour of appearing before it to give evidence. His evidence is said to be in favour of the regular examination of both soldiers as well as prostitutes, as a prophylactic remedy for venereal disease. How far the sentiments of the country generally have advanced towards the acceptance of a legalised system of prostitution, we have yet to learn. That public health and public morality are somewhat at issue in such a system is evident enough. Their reconciliation remains to be settled; and perhaps the Venereal Commission may have satisfactorily arranged the discrepancies between the two apparently opposing facts. The other point is a still more difficult one, if we understand it aright. It is the proposal that the soldier, as well as the prostitute, shall regularly undergo examination to show his freedom from venereal affection. At what rank in the service the examination is to stop, we do not know; whether it is to be limited to the privates or extend up into the higher branches of the military hierarchy. Another question will also here be raised: How will military surgeons approve of the business, should they be called upon to perform it; viz., of regularly passing in review the condition of the soldier in this delicate particular? We apprehend that not many of our Medical brethren would care to accept the appointment of regular examiner to a house of prostitution; and, for a similar reason, we suspect that the Medical army officer may take a moral objection to the business involved in what, as we understand, may be a part of the proposal of the Venereal Commission.—'British Medical Journal.'

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, DEC. 20.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; St. Thomas's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, DEC. 21.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Harveian Society, 8 p.m.—Mr. Sedgwick, "On the Influence of Age in Hereditary Disease."

FRIDAY, DEC. 22.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, DEC. 23.—*Operations* at St. Thomas's Hospital, 9½ a.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

MONDAY, DEC. 25.—*No Operations.*

TUESDAY, DEC. 26.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.; Royal Institution, 3 p.m. Prof. Tyndall, "On Sound." (Juvenile Lectures.)

BOOKS RECEIVED FOR REVIEW.

Australia for the Consumptive Invalid. By J. B. Brown, jun. London: Robert Hardwicke.

Visiting List for 1866. London: Smith and Co.

What Food to Eat. By W. W. Ireland. London: Frederick Pitman.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the Office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

MR. W. PROWSE (Amersham).—The letter is inserted, and the request shall be complied with.

DR. ATTFIELD.—The paper is inserted.

THE OBSTETRICAL SOCIETY OF LONDON.—The report is inserted.

THE HARVEIAN SOCIETY.—The notice is inserted.

GRIFFIN TESTIMONIAL FUND.

SIR,—The following subscription has been further received on behalf of the above fund:—

	£	s.	d.
James Crisp, Esq., Chippenham, per Dr. H. Colborne	0	5	0
Amount previously announced	129	18	3
Received at 'Lancet' Office	9	9	0

Yours obediently,
ROBERT FOWLER, M.D.,
Treasurer and Hon. Sec.

145 Bishopsgate street, Without,
Dec. 13, 1865.

DR. PATERSON'S paper shall appear next week.

AN ASSISTANT.—Ether is, chemically speaking, a base, and is composed of a hypothetical body named ethyle and oxygen.

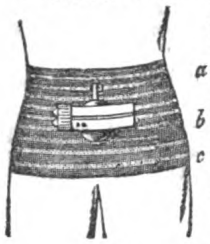
PEREGRINUS.—The Museum of the College of Surgeons is open on Mondays, Tuesdays, Wednesdays, and Thursdays from 12 to 4.

DR. J. B.—Peyer's patches are *not* inflamed or ulcerated in the cattle plague. This fact has now been definitely ascertained.

A STUDENT.—Rymer Jones on the General Structure of the Animal Kingdom.

Huxley's Spiral Abdominal Belt

is constructed on a principle which secures the required support, without being liable to displacement, and is invaluable, when properly constructed, in cases of Pregnancy, Obesity, Ovarian Dropsy, &c. When required, it is fitted with Air-pads for Umbilical, Inguinal and Femoral Hernia, and Band with Air-pad for Prolapsus Uteri and Prolapsus Ani. These goods in addition to Stockings, Thigh-pieces, Knee-caps, &c., supplied 30 per cent. lower than the prices hitherto charged, every article being of the very best quality. — Measures required: Circumference at a, b, c; depth, from a to c.



Priced and Illustrated Catalogues on application to

E HUXLEY,

ORIGINAL COMMUNICATIONS.

ON THE CAUSES ENDANGERING THE LIFE OF THE FŒTUS DURING LABOUR,

WITH SOME PRACTICAL REMARKS.

By C. K. H. PATERSON, L.R.C.P., L.R.C.S. Edin., &c.

In general domiciliary midwifery, it will not, I trust, be disputed for a moment that occasionally is witnessed the occurrence of, or if not, the tendency to "hazardous states," in certain kinds of labour, calculated to endanger fœtal life. Doubtless not a few labour cases during a year, when seen at the first visit by the obstetric practitioner, are to the best of his judgment in their early stage favourable; while frequently, when an examination has been made later, they have become either difficult or complicated labours. Accordingly, it will be allowed, from the occasional uncertainty of the result in the latter, that it is an important and valuable attainment in midwifery practice to be able to make a right discrimination between the nature of the presentation in each individual case, from that of others known to happen, as well as to determine in time when to proceed in aiding the parturient woman. Whether it be in administering needful nourishment or other means internally or by the mouth, or by having recourse to artificial interference with the same end in view—namely to procure her delivery safely for herself and child. Having thus premised, I shall now proceed to state my views in detail, though briefly, as follows:—

How far the tendency oftentimes in difficult and complicated labours to endanger fœtal life may be obviated, must undoubtedly depend much on the kind of presentation, and how such may be managed. The putting off too long, or not sending for proper Medical assistance in time, often endangers fœtal life.

The management of cases of lingering or difficult labour, though there is no occasion for over-anxiety, provided they are seen in time, and when properly attended to, often ends well to the fœtus. Cases of difficult labour have hitherto often come under my notice, with cephalic presentation chiefly, not a few of which, as might be expected, were accompanied in primiparæ with rigidity of parts, and the labour difficultly and gradually went on, owing to the os uteri and other parts taking in some of these a much longer time than ordinary to dilate and relax before the fœtal head was sufficiently advanced for delivery, notwithstanding previous means were used internally.

Where, on the other hand, there were present (rendering the labour for the time they lasted more than usually difficult) signs in maternal passages of coiling of the fœtal cord round the neck, and when ergot of rye was early made use of and before the head was pretty well advanced, I have seldom seen the expected results accruing from the latter favourable to the fœtus. In my own practice, coiling of the cord round the neck or body of fœtus has been found frequently in the child-births of multiparous woman, and I have observed such an occurrence frequently to endanger fœtal life in no small number of cases.

Misplacement or unnatural shortness above of the cord, when the fœtal head is in the pelvis, and there is found plenty of room for the latter to pass through, may be suspected to exist, if during the continuance of pretty strong and regular pains for some time, the head slowly advances for a given time, and it is ascertained that it retreats after each pain, while the os uteri has become well dilated. Nevertheless, and although relying a good deal on the above sign of the existence of twisting of the cord, I have used ergot less than formerly, preferring non-interference instead of pushing cases of this kind when there was no urgent symptom calling for active and immediate aid, and I have never had to regret doing so. But should the cord be supposed to be round the neck of the fœtus, and notwithstanding it may be the chief cause of retarding the progress of the labour, when not continuing beyond a reasonable time, it is even safer to omit than to have recourse to ergot, and there is less danger to fœtal life, except the labour is near its termination, and then it may be found very serviceable at times. Still there are cases, doubtless, in which it is often necessary to give ergot, and with excellent results, as when the labour is hindered by insufficient uterine action—membranes previously broken—the os uteri being well dilated at the same time, and also ample pelvic room, no discordance between the bony parts and fœtal head, the latter having descended to the lower pelvic outlet or hollow of the sacrum. While, on the contrary, when ergot is given too early, or some time before delivery can be safely effected, or after the liquor amnii has flowed away spontaneously and prematurely, or has been too soon let off artificially, and the os uteri not much dilated, nor soon dilatable, the head not advancing in proportion to the length of time the parturient woman has been in labour, and more especially if, after administering ergot, the labour is not within a reasonable time afterwards terminated, or should it be allowed to linger on instead of adopting artificial interference as soon as the case is favourable for, or demands it, and the measure is not had recourse to, at a period of delay of this kind, it is rare, in my humble experience, to have a live child born in a labour managed as just described. Hence, when the afore-mentioned signs are found in the maternal passages, of the hindrance of the fœtal head during labour from coiling or twisting of the umbilical cord round the neck or other parts of the body of fœtus, as the cord must consequently be much shorter from this circumstance, but if not so, at any rate, it is generally longer in its duration and more difficult; and to my mind it has seemed to be both safer and better practice to omit ergot in such kind of cases until towards the close of the labour, on account of the occasional subsiding of the maternal pains, when at this stage its administration in the usual form and doses will tend less to endanger fœtal life and it will also shorten the labour.

In reference to the above remarks, my usual practice for years past has been, and is still, to *let Nature for a reasonable time do her own work*, and to render extra aid only if requisite, for the safety of both mother and child.

I shall merely at present add a few of the causes in the maternal passages that have conduced more or less to endanger fœtal life in cases attended by me—viz.:—

The fœtal head, when it had rested too long on an unyielding perinæum, or when there is rigidity of parts, especially early and late in life (first pregnancies at full time).

In presentation of the head, it being only expelled, and while immediately after its expulsion is attended with too much delay in delivery, on account of want of sufficient pains to expel the shoulders when large.

In flooding and breech cases from not getting the head when large speedily delivered. In unusual projection of the promontory of the sacrum, in preventing the head from descending in consequence of too little space.

Fœtal head too long delayed in pelvis during labour, from inefficient uterine action, or unusual rigidity of one or more parts.

Prolapse of cord by side of head, or coiled round the neck and other parts of the body of fœtus.

Fœtal umbilical hernia when large.

Fœtal head (male) firmly ossified, and also rather larger than ordinary, and I may mention in addition, maternal mental impressions.

With all these complications we have certainly a wide field for highly important and valuable investigation, as well as interesting questions, obstetrical and physiological, and especially in a medico-legal point of view.

"CYCLOPS'" THIRTY-THIRD LETTER ON PHYSIOLOGY.

To VIGILANS.

SIR,—If we take a sheep's kidney, for instance, enclosed in fat, it will be found that the cortical part is least covered; indeed, in many cases this part may be seen through the fat, while the largest and densest quantity is always on the opposite side. This side is very different in shape to the cortical, which forms a half circle, while the other forms two, with a much depressed centre, representing a comparison between the natural appearance of the nates and the anus. If care is taken in making a clean section through all its substance, from the rounded or cortical side down to these parts, and a perfect incision of the calices and pelves made, without cutting through the entire kidney, but leaving a hinge about the contracted portion, we find just within the pelvis a small piece of fat. In the dissection of this, there will be found some hard semi-cartilaginous bands, surrounding this fat. It has been noticed by casual observers, who are fond of kidneys, that if this part, including the pelvis, be cut out and put into the mouth and masticated, this cartilaginous substance is very apparent. Many persons cut this away entirely and leave it, others cut it off first, masticate it, and put out the hard mass; but it is patent to everybody, whether he is or is not on anatomist, that this semi-cartilaginous substance is always present. It will also be noticed, that there is a true skin or fascia to the inner side of the investing layer of fat, as well as another true skin to the kidney itself. The fascia or skin of the fat from all these parts concentrates round the two nates, and becoming thicker and denser as they dip into the anal portion, and thus, as is were, to secure a free fatty communication with the whole bulk of fat within. It matters not whether it is a single kidney like a sheep's or a pig's or the many lobulous portions that make up the kidney apparatus of the bullock. The pelves of each have a direct fatty pith going into them, which is secured and protected by the cartilaginous arrangement I have mentioned. This at once shows that there is a communication from the body of the fat and that much of the aqueous portion of the fat is continually flowing into the pelvis of the kidney at all times. This being an inorganic fluid, is provided by Nature to mix with the small quantity of organic salts, the principal of which is urea, formed from the blood in the cortical part of the kidney, and, according to the pressure of the surrounding fascia and skin of the fat, so this aqueous matter is pressed through it. The structure here resembling the nates and terminating in the anal portion, shows a funnel-shaped formation which assists the filtering of the aqueous portions. The provision of the semi-cartilaginous rings are similar in use to the cartilaginous rings of the wind-pipe and prevent the communication between the pelvis of the kidney with the great body of fat from being closed or interrupted. It needs no speculation of diuretic drinks exciting the kidneys to greater action, nor of any distinct communication from the stomach or anywhere else direct to the kidneys, to account for their excessive or often rapid action. No fluids which we drink in any quantity can of themselves go direct to the kidneys; nor, as physiologist say, first into the blood and then into the kidneys. Our blood keeps up its normal quantity and pursues the even tenor of its way, and its circulation; but into what a disturbed state would the body soon get if the volume of the blood was to be alternately increased so inordinately by the fluids taken into it, to be only decreased by the action of the kidneys. For the kidneys, like the blood, pursue the even tenor of their way, and only do what is required of them, and that is, to remove what urea is not wanted in the lower extremities. This fact must always be borne in mind, that fluid like everything else taken into the body, resolves itself into primary elements. It is not yet admitted that we micturate beer, or claret, or whiskey, or anything fluid as it is taken. Therefore, why should we imagine that water is an exception?

Here again the laws of the gases rise in judgment against our physiological dogmas. If more hydrogen is formed, oxygen is sure to come to its union, and these combinations always tend to fat formation by inspissation, but if, on the other hand, when excess of fluids are taken, they become first resolved into their gaseous elements, and fluids being reformed, while inspissation being impossible, they are filtered through the natural receptacles, the fat; some passing off through the skin and cellular tissue and the others through the pelves of the kidneys. Hence it is that persons drinking largely, and having to micturate in proportion, pass through their kidneys large quantities of inorganic fluids. Some men I have seen pass several pints after a dinner, when the wine has gone round freely, and it is curious to observe that if they can withhold the act of micturation, they can retain all the elements, but if once they begin to micturate, an exciting action having been set up in the surrounding fat of the kidneys, they require to relieve the bladder almost every half hour. Now, in urine thus made, there is very little urea, or in fact any salts eliminated from the blood by the kidneys, thus showing that the blood is wholly undisturbed, or much influenced by these large libations. If we only reflected for one moment that all these pints of fluids—call it, if you will urine—actually came by elimination from the blood,—in what state would the system be in, or into what state would it get? The question which naturally arises then, is this: Is the whole bulk of urine voided at any time, *a robbery of the blood?* The answer is, it cannot be! There is not a sensible man out of the Profession, or one not bound by any of its tenets, or physiology, that can believe for one moment that the urine is a *robbery from the blood.*

Let us take the three most distinctive characters of the urine, apart from its true and normal state, whatever that may be, which is quite unnecessary to particularise here. There is first the urine which is sparsely secreted, when an individual can go from morning to night and not want to micturate. This is very moderate in quantity, and rather high-coloured, and contains large proportionate quantities of urea and blood salts actually secreted by the kidney. Still, eighty or ninety per cent. is from the inorganic fluids filtered through the fat, and these fluids are more or less very pure in their character. Probably this condition has also been coupled with exercise which has induced an excess of radiation through the skin—in short, more perspiration. Here the fat has filtered the aqueous humours through the cellular tissues. Now, physiology does admit that when an individual at times perspires more freely, he voids less urine. Here then we can make a fair physiological deduction. The second distinctive character of the urine is that which seems to be passed tolerably clear, but of much lighter colour, but on cooling it becomes of a pea-soup consistence, and deposits a large amount of lateritious and other sediments, and is made more frequently than the first. Now, does this show in its analysis greater organic elements such as may be said to be eliminated from the blood? probably it may to some extent. But then are we not to give to the inorganic elements which furnish its greater bulk some share of this morbid action? The inorganic fluids must surely become at times in a morbid condition, and instead of the natural filter, the fat, depositing a clear fluid, it will have mixed with it perturbed elements, therefore, this state of the urine as much depends upon this condition of those elements as certain alterations of the basic salts do upon the condition of the blood. Now, both these conditions of the urine are capable of being retained by the bladder. They do not press for their immediate voidance. There is an intelligence in the bladder itself that shows it can bear their presence during the proprietor's pleasure to void it. The third abnormal character of the urine differs in all this; it is that which is of a pale straw or citron colour, sometimes approaching even that of slightly tinted water. Now this has very little of the organic elements of the blood, and the kidneys themselves have had very little to do with it as secreting organs. This urine is made frequently and in large quantities, and what is more, cannot be retained. It is most irritating to the coats of the bladder. It occurs at such times when there

is very little radiation from the skin or even a tendency thereto. Radial heat seems to have stopped from the centres to the surfaces, and taken that peculiar reverse action from the surfaces to the centres. The consequence is that the fat about the kidneys relieves the body of its surplus fluids and filters them through these organs. Can anyone, however bigotted he be to received opinion, say that this great quantity of mere fluid is a *robbery of the blood*. If it is, it must come through the liquor sanguinus or serum. Let me ask the chemist whether he has ever found in this peculiar urine any element at all resembling the serum of the blood, or that the serum of the blood could at any time furnish so pure a fluid?

Again, it contains scarcely a trace of urea or any of the elements of the blood. It could not, therefore, be possible for the kidneys alone in a few hours to take such amounts of water from the blood to the exclusion of the urea and other salts, especially when the offices of the kidneys are only to do this and *not to remove water at all*. The very construction of the kidneys shows this in a marvellous degree, and what Nature has alone designed them for. Their duty is simply to remove what is not wanted, but their other design is to be a receptacle for relieving the body at certain times of the inorganic fluids, which serve again to dilute their own secretions, and which evidently could not pass without this provision. As we have seen in the third condition of the urine, which is only aqueous and almost purely inorganic in its character, the kidneys are a ready receptacle to pass off through the bladder what certain states and conditions of the body have wisely directed there. As this last condition is sometimes very troublesome and when it continues inordinately, is often very weakening, the physician is called in to relieve the patient. Well, the simple remedy is immediate active physical exercise to such an extent as to use up these fluids and by inducing perspiration to direct them through the cellular tissues to the surfaces. But if this cannot be done either from accident, old age, or impossibility of physical exertion, then to act on the mucous membranes and primæ viæ by cathartics, or aperients, or drastic purges, according to circumstances.

I wish to show that whatever I write has a bearing on the practice of Medicine. Let me observe, that in diarrhœas, how little urine is made, and that in cholera, none! A person recovering from an attack of cholera, the first beneficial symptom is a return of the power to pass urine, and the worst symptom leading to an unfavourable prognosis is the total inability to do so. And now let me ask what is the state of the blood in such attacks of cholera? Is it possible that in the almost anæmic condition of the patient after such an attack, and the great loss of fluids generally, that the blood could bear the *robbery of the urine*, supposing, as it is asserted, that the urine is entirely of itself a secretion from the blood. The smallest grain of common sense brought to bear upon all these facts must show the fallacy of the present doctrines of the kidneys, and their supposed secretion of urine, and all the elements that pass out of the bladder. I have long looked with some degree of mistrust on all these things when I have passed through the wards of our hospitals and seen the numerous test tubes and apparatus for testing and trying the specific gravity of the urine of all the patients. Nevertheless, the physicians must believe that all they see there, in every case they test, shows the condition of organic blood elements alone.

The facts I have now mentioned have evidently never occurred to their minds, for they seem to have taken no consideration whatever of the inorganic elements of the body; nor have they ever thought how much every part of the system was indebted to them; nor to the sources from which they were derived, or the uses to which they were applied, nor to the gases to which so much vital power was due. Without all this and more, I tell them they will never be able to make head nor tail of disease nor ever find out its laws; for it has laws, as everything else in Nature; nor can they ever pretend to treat disease in any scientific or certain manner, until they sweep away and abjure many of their darling tenets, and begin afresh to unravel the truths of Nature, which a severe study of physiology can alone impart. At present, there is little truth to be found in all their books and dogmas and considering the age in which we live, the Practice of Medicine is its greatest opprobrium.

We are told that everything must come to an end. The year will soon come to an end, and these letters have now come to an end. I am fully aware of my boldness in having written much new matter, which I have been compelled to do in a very limited way. If, however, there is any man who takes exception to what I have written in these THIRTY-THREE LETTERS and will in a fair spirit attempt to refute anything I have said and will publish it in THE MEDICAL CIRCULAR, I will engage to answer him. It is my intention at some future time to collate these letters, and, with the addition of more important matter, to publish them in another form. Until then, Respected Vigilans adieu, and Reader, farewell.

I am &c., CYCLOPS.

[The Editor begs to state that he does not hold himself in any way responsible for the opinions expressed in the foregoing letter.]

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, DECEMBER 5.

Dr. PEACOCK, President.

Dr. RAMSKILL showed a specimen of

RUPTURE OF THE HEART.

A woman, sixty-one years of age, was seized about an hour after breakfast with acute pain in the region of the epigastrium. She complained of feeling sick, her face and lips were very pallid, the pulse scarcely to be felt. When told to go to bed she got up and walked into her bedroom. At 1 o'clock, when Mr. Couper, her Medical attendant, called, she was in a doze. A consultation was arranged with Dr. Ramskill at 5 o'clock, but she suddenly died. Mr. Couper was hurriedly summoned to her bedside; she was heard to make several deep-drawn inspirations, and then died. Ten minutes before death she had been talking to her son-in-law. The post-mortem examination was made by Dr. Bazire at the request of Dr. Ramskill. On slitting open the pericardium, it was found to be filled with black blood, partly fluid and partly coagulated (but not firmly, of the consistency of black currant jelly), in a uniform layer round the heart. Pericardium healthy and normally transparent. Heart small, very soft, and flabby; this softness contrasting with the *rigor mortis* of the body. On removing it, black liquid blood was seen to ooze out of a rent in the anterior wall of the left ventricle, about midway between the apex and base, and close to the inter-ventricular septum. The rent measured about a quarter of an inch in length, and was merely linear. The wall of the organ at that part felt softer and thinner than elsewhere over an area of the size of a shilling. There was a good deal of yellow fat deposited on the heart. The coronary arteries were not atheromatous or calcified. On laying open the left ventricle, the inner aperture of the rent was found to be partly covered over by a pretty adherent fibrinous clot, but not occluded. Two or three columnæ corneæ were lacerated, and the thin portion of the wall already mentioned was stained of a dusky red colour from imbibition. The rest of the organ was, on the contrary, paler than usual, and the consistency of its texture was so diminished that it tore easily under the least pressure. The mitral valve had lost its transparency, but was neither puckered nor rough, and the left auriculo-ventricular orifice seemed natural. The right ventricle was completely collapsed, and did not contain a single drop of blood; its walls were

remarkably thin; they were soft also, but less so than those of the left chamber. The pulmonary artery and valves were healthy; the tricuspid valve was normal. The semilunar valves of the aorta felt hard, almost cartilaginous, along their attached border, but were normal in their unattached or free portion. Small patches of commencing atheroma could be seen all round the circumference of the aorta at its origin. The artery higher up was healthy.

Mr. CALLENDER showed a specimen of

FRACTURE OF THE CARPAL END OF THE RADIUS AND OF THE SCAPHOID BONE.

A male, aged forty-five, fell from a height and fractured his skull, his right thigh, and his right radius. He died five hours after his admission into St. Bartholomew's Hospital. On examining the wrist the radius was found to be broken at its carpal extremity, four-tenths of an inch from the joint, the proximal portion of the bone being driven into the distal, completely crushing it, the fracture extending in many places into the wrist joint. The proximal portion of the shaft was also displaced inwards, carrying with it the ulna, the latter bone being torn away from its triangular ligament, to which the tip of the styloid process remained attached. The scaphoid was broken across about the middle, the fissure extending through the bone to the articular surface for the os magnum. The entire hand was displaced backwards and to the radial side, the ulna projecting. The displacement was easily reduced by simple extension, but the outline of the radius remained irregular, rough projections of bone being felt chiefly on the dorsal aspect. The specimen shows the manner in which, when driven with great force, the proximal portion of the radius is forced into the carpal extremity, breaking it up into many pieces, splitting into the wrist joint, and, in this instance, fracturing the scaphoid bone, the latter being a rare complication. "Indeed," Mr. Callender said, "there exists to my knowledge in this country only one specimen in which an injury to the carpus has been sustained in conjunction with any such hurt to the radius. The impaction of the shaft, by which this mischief was occasioned, was prevented from locking together the two portions of the bone by reason of the great comminution which has scattered in all directions the carpal extremity of the radius; it is evident, however, from the position of the shaft, and from the nature of the injury to the ulna, that the impaction was established in a direction forwards and to the ulnar side in the manner which I have described elsewhere. One point of interest remains to be referred to. The comminution caused two fragments of bone to be tilted backwards, and between the two the tendon of the extensor carpi radialis brevior was fixed and firmly compressed, so that it could not be freed from its entanglement until after removal of the soft parts surrounding the portions of broken bone."

Dr. PEACOCK showed a specimen of

DISSECTING ANEURISM ORIGINATING IN RUPTURE OF THE COATS OF THE AORTA AT THE DESCENDING PORTION OF THE ARCH.

This specimen, which was sent to Dr. Peacock by Mr. Hacon, of Hackney, was removed from a man forty-five years of age, a wine cooper, but who had not been accustomed to active exertion. On January 31, he went out into the country with a party of pleasure, and while there he was seized with violent pain in the epigastrium and severe dyspnœa. The attack subsided, but he had several recurrences, and died suddenly in one on February 7. After death a very large accumulation of coagulated blood—several pounds—was found in the posterior mediastinum and behind the left costal pleura. It had separated the pleura from its attachments, and compressed the lung, but there was no blood in the pleural cavity or in the sac of the pericardium; a small coagulum existed also in the anterior mediastinum. On further examination the blood was found to have escaped from a rupture of the aorta at its upper surface, situated immediately behind the origin of the left subclavian artery. The coats of the aorta were torn through by a transverse slit extending around about one-third of the circumference of the vessel, and partly separating the subclavian artery from that vessel. This laceration had allowed the blood to pass between the fibres of the middle coat, to separate the middle from the external coat, and to penetrate to the cellular tissue outside the aorta so as to produce the extensive effusion found in the posterior mediastinum and behind the left pleura. From the transverse rupture, a second, following a longitudinal direction, extended for a short distance the arteria innominata, and involved the origin of the left carotid artery, but this only partially penetrated the coats. From it the blood had passed from between the layers of the middle coat of the carotid, separating them and forming a passage extending upwards of an inch from the origin of the vessel. The ascending portion of the arch of the aorta was somewhat dilated, and its coats were throughout in places atheromatous and thickened. The heart and its valves were stated by Mr. Hacon not to have been diseased. Dr. Peacock remarked that the case was interesting in several respects. 1st. The seat of the rupture at the descending portion of the arch was unusual. Of the cases collected by Dr. Peacock, and of which an analysis was published in a previous volume of the 'Transactions' (xiv.), eighty in number, in eight only were the internal ruptures in this situation, and the five others subsequently referred to (vol. xv.), none had the same position. 2ndly. The termination by the escape of blood into the posterior mediastinum and behind the left pleura, while the pleural and pericardiac cavities were free, was almost unique. Of the cases previously collected, in which the rupture had the same situation as in this instance, none terminated in the same way, and of those in which the internal ruptures were seated in the ascending portion of the aorta one only terminated by bursting into the mediastinum—in that case the anterior mediastinum. 3rdly. The prolongation of life for seven days, and the very large extravasation of blood which was found after death, were also remarkable; though generally when the rupture was more distant from the heart, life was more prolonged than in the cases where the injury occurred at the origin of the aorta. It is not clear from the specimen whether the blood had commenced to escape into the mediastinum at the time at which the injury first occurred, or whether, on the contrary, the rupture was then partial, and became entire only shortly before death; but it seems probable, from the very large amount of blood which was effused, and its firmly coagulated state, that the former had been the case.

Dr. PEACOCK also exhibited, in conjunction with Dr. WALE HICKS, a specimen of

ULCERATION AND STRICTURE OF THE ŒSOPHAGUS.

It was removed from a man, aged fifty-five, a smith, of intemperate habits, who died in St. Thomas's under his care. He had œdema of the lower extremities and chronic bronchitis, and when first admitted the urine was slightly albuminous, but though several times examined no albumen was subsequently detected. He died with symptoms of effusion on the brain. After death it was ascertained that about twelve months before he was suddenly seized with vomiting, and brought up blood, and ever afterwards had had difficulty and pain in swallowing, so that he was not able to take any solid substance.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on the 14th inst.:—William Matthews Robart, Wilmot street, Derby; George Richard Cooke, South Belgravia, S.W.; Nathaniel Edward Davies, Llanrwst, North Wales; Joshua Price Edwards, Tunstall, Staffordshire; John Humphreys, Cheltenham Branch Dispensary; John Shirley Steele Perkins, Exeter; Charles William Philpot, King's College Hospital; John Harrington Wright, Lower road, Woolwich.

The following gentlemen also on the same day passed their first examination:—Charles Adcock, Queen's College, Birmingham; William Stanger, Guy's Hospital; Robert Lewis Willcox, King's College Hospital.

THE MEDICAL CIRCULAR.

WEDNESDAY, DECEMBER 27, 1865.

THE TERMINATION OF THE HUNTER CASE.

The last act of the drama in which Robert Hunter lately figured has been played out, and his two assailants, having been found guilty of a common assault, have received judgment. One, who was the husband of Mrs. Merrick has been sentenced to pay a fine of 5*l.* and to be imprisoned until the fine is paid, and the other, who appears to have been guilty of a very savage and brutal act of violence in biting Hunter's ear, has been condemned to two months' imprisonment without the option of paying a fine.

It will, probably, be thought that substantial justice has now been done to all parties concerned, and the whole affair may, therefore, be buried in oblivion. Hunter would have received much more sympathy, if he had sought the confidence and goodwill of the Profession to which he claims to belong, but whose support he has forfeited by the questionable manner in which he has sought to introduce himself into practice. Having obtained, as he asserts, a diploma in Medicine from the University of New York, he would have had no difficulty in passing an examination and obtaining a licence or diploma to practise his Profession in this country, and he might then have entered with honour into any field of labour which he chose to select. But, instead of doing so, he commenced a system of indiscriminate advertising in the public newspapers, which actually published his pretentious pamphlets (no doubt for a due consideration) as scientific articles among their editorial matter! Such a course was equally reprehensible in the person who attempted such a scheme, and in the journals which encouraged it, and the whole proceeding naturally excited the disgust and the contempt of the Medical Profession.

But, as we have previously remarked, it does not follow that because a man is guilty of issuing unprofessional advertisements, he is, therefore, to be convicted of a rape, nor, we may add, does it place him so far out of the pale of society that he is to be bruised and beaten, and to have his ear bitten off with impunity. As to the charge of rape, the jury who tried Hunter have shown that they believed him innocent, and we have no fault to find with the verdict. A great degree of solemnity was given to this charge by the statement that the lady who made it was dying of consumption, and on the examination before the magistrate it will be recollected that that functionary actually took her depositions in the sick room; but, as she was able to appear at the first trial at the Old Bailey, and also at the second, when her husband and brother were tried for the assault on Hunter, is to be hoped that her malady is not so serious as it was at first supposed.

THE MURDERS IN HOLBORN AND RAMSGATE.

The man Forward, or Southey, who, in the summer of the present year, committed the horrible crimes of murdering three of his children by poison in London, and his wife and another child by shooting them at Ramsgate, has been tried and found guilty of the latter offences, and has been sentenced to death.

The peculiar atrocity of the deeds themselves, and the antecedents of the murderer, place him almost beyond the reach of human pity, and if, instead of the ceremony of a trial, he had been subjected to the same rapid fate which he inflicted upon his victims, and some Nemesis had strangled or drowned him, or shot him, at, or immediately after, the period of the murders, none, we believe, would have commiserated his doom.

As it is, he has passed through the ordeal of a trial at law, and the defence of insanity has been set up, but without success, by his counsel. The violence of his conduct during the trial, we are told, only convinced all those who were present that he was feigning insanity, and unquestionably the evidence in support of the view that he was really insane, was exceedingly weak. It was, indeed, so weak that we wonder it was brought forward at all, and that his counsel did not content himself with making a speech. At present, we are not yet wholly convinced that he is not insane, but the clumsiness of the attempt made to prove him so, was more injurious than useful, and we do not wonder that it failed.

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL REFORM.

To the Editor of the Medical Circular.

SIR,—I must again crave your indulgence for space, to inform the Poor-law Medical Officers that I have prepared the draft of a Bill on the subject of Poor-law Medical Relief, and have transmitted it to Dr. Henry, the secretary of the British Medical Association, for the opinion of the Poor-law Medical Relief Committee of that Society, as the annexed letter will explain.

Since the last publication of the list of subscribers, I have received the following sums of money, which I have carried to the account of the Association:—

Dr. Sankey, Hollingbourn, 20s.; David Skinner, Hollingbourn, 5s.; H. T. Wood, Tavistock, 5s.; T. Robinson, Cheadle, 5s.; W. Sheppard, Ashford, West, 10s.; W. Woodward, Worcester, 5s.

I am, &c.,

12 Royal terrace, Weymouth, 18 Dec., 1865.

RICHARD GRIFFIN.

Copy of a Letter to Dr. Henry, Secretary of the British Medical Association, Dec. 5, 1865.

"MY DEAR SIR,—If the Committee of Poor-law of the British Medical Association think they can do anything in the forthcoming session of Parliament, I should say no time ought to be lost in determining on the steps to be pursued. For this purpose I send you the draft of a bill which, if your printer (at the expense of the Association) would print and forward a copy to each of the Poor-law Committee, they might then make their remarks upon it, and submit them to you, and if you find we are likely to agree, I should suggest that the Poor-law Board be asked to receive a deputation next month, and that we should then urge the President to bring in a Government measure on the subject. Failing of success with the Board, we

should endeavour to procure an independent member, of some weight in the House, to introduce a Bill.

"I am, &c., "RICHARD GRIFFIN."

To the Editor of the Medical Circular.

SIR,—Will you kindly find space in your Journal for the following remarks which are addressed to the Poor-law Medical officer by one of themselves. I would simply ask them if they are disposed to allow matters to remain as they are, resting satisfied with the small modicum of justice already gained, or do they wish that their claims for redress should be perseveringly and unflinchingly preferred as Mr. Griffin proposes. For my own part, I fully agree with our Chairman, and will gladly and hopefully join in his endeavours to gain for us a just and complete recognition of our services. I believe that gentlemen generally are inclined to take the same view, and would, I feel sure, not object to subscribe towards the Reform Fund if they were personally or by letter applied to for their contributions. I would beg all those gentlemen, who are of our opinion, and think that the movement should be persisted in to notify their willingness and determination by sending a few postage stamps, enclosed to Mr. Griffin, at Weymouth, with as little delay as possible. I am &c.,

Amersham. WM. PROWSE,

HYPODERMIC TREATMENT OF CHOLERA.

To the Editor of the Medical Circular.

SIR,—As the chief obstacle to the successful treatment of Asiatic cholera consists in the fact that medicines introduced into the stomach are not absorbed into the system. It appears to me that the subcutaneous injection of appropriate remedies ought to be followed by more satisfactory results. At any rate it is almost certain that the absorbents in other parts of the system retain some amount of activity for a considerable time after all power of absorption has been lost in the gastro-intestinal canal. Now, it is a well-known and recognised fact, that medicines taken by the mouth lose their power long before the stage of extreme collapse shows that most vital actions have ceased, or, at any rate are in abeyance for the time. This intermediate period then is the time during which it appears to me that the hypodermic introduction of remedies (used, of course, together with the most approved external applictions) promises to do more for us than the administration of drugs by the mouth has as yet been able to effect. I have not seen anything written on this subject, in connection with cholera in any of the Medical journals, and my object in writing these few lines will have been effected if I succeed in eliciting the views of some of the Profession on the subject. I am, &c.,

OXONIENSIS.

THE BELFAST POOR-LAW GUARDIANS.

To the Editor of the Medical Circular.

Sir,—As you were so very kind as to allow me space on a former occasion in your able and most impartial journal to make a few remarks with respect to a correspondence that took place about the month of November, 1861, between an English gentleman from Leeds, named Mr. Joseph Roundtree, and the Belfast Board of Poor-law Guardians respecting the harsh treatment exhibited towards the insane and sick poor of the Belfast Workhouse; and when that honourable Board did nothing at that time but merely pooh-pooh the remarks of the humane English gentleman as false and unfounded, respecting the state of the unfortunate and helpless insane inmates of that great model establishment. So the cat is let out of the bag at last, as you will observe by a Belfast Newspaper, that I have taken the liberty of sending you, and in which you will see that a very sharp discussion has taken place on Tuesday last among the Belfast Board of Guardians themselves, and in which it is now even admitted by themselves, that the state of the insane confined in the Belfast Workhouse is not even yet by any means what it ought to be.

I am, Sir,

Your most obedient servant,

N. M.

Drogheda, December 18, 1865.

The following is the report referred to:—

"Your committee, having inspected the idiot wards, are sorry to find the accommodation very deficient, particularly the female portion, where we have ninety-six patients and eighty-five beds, and a day-room sixty feet by eighteen. The male portion is also very much crowded, there being fifty-eight patients and a day-room thirty-five feet by eighteen. The committee would suggest, to meet this difficulty, that one-half of the school building should be set apart—which would provide ample accommodation for double the number at present in the idiot wards—and the committee would suggest that, until this change could be carried out, the following temporary accommodation should be provided—namely, the ward in the male idiot side adjoining the female department to be given up to the female idiots, and a lower ward to be given up to the male idiots; and the lower ward in the centre of the main building adjoining the nurses room to be converted into an infirmary ward."

PARISIAN MEDICAL NEWS.

DIAGNOSIS OF CANCER OF THE STOMACH.

In one of his last lectures, M. Beau invited attention to three cases of cancer of the stomach, which were at the time placed in his wards. The first patient was an old gardener, aged seventy-seven, labouring under dyspepsia. This man had rapidly lost flesh, was liable to frequent fits of vomiting, and complained of pain and tenderness on pressure in the epigastric region, which suggested the idea of organic disease of the stomach. The second subject was a woman, who, at the period of her admission into hospital, suffered from obstinate vomiting, which yielded to the application of a blister to the epigastric region, but recurred after an interval of three weeks. Another woman who occupied a bed in the same wards, in addition to the functional symptoms indicative of cancer, bore a tumour *in the* abdomen.

Now, although the functional symptoms and physical signs of cancer of the stomach are fully described in every work on pathology, several of them present peculiarities to which sufficient attention has not hitherto been conceded, and to which the late lamented Professor deemed it expedient to advert.

Vomiting, which, coincidently with other indications of dyspepsia, occurs in subjects affected with cancer of the stomach, is viewed as a characteristic symptom of cancer. It is not, however, invariably observed in every case. A carcinomatous tumour may be present, readily discoverable on palpation, and yet neither emesis nor any very obvious disturbance of the gastric functions may exist. M. Beau has occasionally noticed this apparent discrepancy *in patients* bearing a tumour which could be easily felt, and *in* whom dissection subsequently removed after death, all doubt as to the nature of the disease. In these individuals gastric derangement had supervened but a short time before death.

Intercostal neuralgia is another frequent and often most distressing indication of cancer. The Emperor Napoleon complained in his last illness of excruciating pain beneath the left breast, which he compared to stabs with a penknife. This neuralgia occurs, however also in common dyspepsia unconnected with carcinomatous diseases.

The discovery of the characteristic tumour often requires minute attention. Its situation is extremely uncertain; it has been found in different parts of the abdomen, where at first the idea of seeking it would scarcely occur. Thus, it has been detected in the right flank, where its presence

explained by the tendency to displacement of the affected viscus. This circumstance adds considerably to the difficulty of diagnosis, because growths of another nature not unusually accompany dyspepsia. A mistake may, for instance, be induced by a part of the enlarged liver, or more commonly by stercoral accumulations. In this case an error is readily accounted for, because accumulations of fæces may occur both in dyspepsia and in cancer, and do not entirely preclude the occurrence of small and deceptive daily evacuations.

In cancer of the stomach, a considerable degree of anæmia is generally present, but it has peculiar characters by which it may be discriminated from analogous conditions of the system induced by a different cause. The loud arterial murmur indicative of chlorosis is not here to be found. M. Beau related the case of a patient who, under the depressing influence of sorrow, became affected with severe dyspepsia. On auscultation, loud vascular murmurs were heard in the heart and large arteries. The same patient applied again to M. Beau after an interval of several months; he was still weighed down by grief, but his condition in other respects was changed. A cancerous tumour had formed in the epigastric region, where it was plainly discernible on palpation, and its development had coincided with the disappearance of the vascular murmurs. As the mechanical cause of arterial souffle is not accurately known, it is difficult to account for its cessation in cancer; we may, however, remark that although the chlorotic murmur is not audible, the pulse is small instead of being full and soft.

Persons affected with cancer of the stomach do not, like dyspeptic subjects, present in general any analgetic or insensible spots on the surface of the skin. In one case of cancer only has M. Beau been able to detect the presence of this singular phenomenon, and he regarded it as entirely exceptional.

The modes of termination of cancer of the stomach are but too well known. At a certain period of the disease, even liquids are rejected by the stomach, and fatal marasmus promptly supervenes. In some instances, death is the result of hæmorrhage or of peritonitis, which is occasionally the first indication of the carcinomatous affection.

Of course no effectual measures of treatment can be resorted to in cancer; but if any doubt exists as to its nature the remedies applicable in dyspepsia should be prescribed, and thus some slight, though often only temporary relief may be gained. In two of the cases above referred to, for instance, the vomiting was arrested for three weeks by the application of blisters, and appetite was partially restored. Intercostal neuralgia may also often also be calmed by the same method; in short, the practitioner should interfere actively, because the treatment appropriate for uncomplicated dyspepsia, may as a palliative prove useful in confirmed cases. —'Journal of Practical Medicine and Surgery.'

MENINGITIS.

Professor Roger has resumed this subject during the present session, and in opposition with the prevalent opinion, contends that uncomplicated cerebral meningitis is as serious a disease as the tubercular form which is invariably fatal. When a practitioner has the ill-fortune to meet with a case of meningitis in a child, he assumes that no tubercular deposits have formed on the cerebral envelopes, in the forlorn hope that some chance may still remain of preserving life. This, according to M. Roger, is a delusion which should not be entertained, and the dereliction of this erroneous opinion will have the twofold effect of enhancing the merit of the physician's efforts, while it will guide him to a more correct prognosis. It is, of course, not unreasonable to hope that in simple inflammation the morbid exudations may be absorbed, and that a cure may possibly be effected; whereas, when tubercular granulations are present, the permanency of the cause must inevitably lead to disastrous results. This course of reasoning seems theoretically unimpeachable; but in point of fact, one kind of meningitis is as fatal as the other, because simple inflammation is not confined in its action to one limited region of the brain, but promptly extends to the whole of its convexity, or invades the entire base of the organ. This form of disease is, moreover, quite as formidable as tubercular meningitis, because the anatomical changes it induces consist in thick false membranes, in copious morbid secretions, and collections of puriform matter which lie between the membranes, penetrate into the cavity of the arachnoid, and are not included between this membrane and the pia-mater, involving only a small part of the vascular network of the convolutions. These anatomical changes are, therefore, utterly incompatible with the continuance of life, or, at least, present but the very faintest chance of cure.

At all ages pleurisy and pericarditis occur in an uncomplicated form; but it is not so with meningitis or peritonitis, which are both almost invariably the result of some other affection. Otitis, for instance, not unfrequently gives rise to meningeal inflammation; and during the present year a case, in point was admitted into M. Roger's wards, with which the Professor used to illustrate his remarks on the connection of cause and effect which exists between both diseases.

The patient was a girl of fourteen, who on the 8th of April consulted M. Roger at the hospital for a severe pain in the right ear, and a puriform discharge from the auditory duct which had lasted four months. The pain had preceded the otorrhœa, and after occasional intermissions had become extremely violent, and the following was the condition in which the organs were found when first examined:—

The pain in the right ear was deep-seated and incessant; severe headache also existed in the right side of the head, and caused the patient to moan uninterruptedly. The least movement, the lightest contact were unbearable, and the girl reclined motionless on her back. The secretion from the ear was fetid, puriform, and flowed copiously on the application of pressure in front of the ear. Inspection with the speculum showed that the membrana was perforated, and that the remains of the membrane were covered with purple granulations, which evinced a great tendency to bleed. In addition, the eyelids were unable to close over the right eye, which remained partially open, and unquestionable paralysis existed of the muscles on that side of the face. The intelligence was unaffected, common sensation and muscular power had preserved their integrity; but a tendency to coma was apparent, broken occasionally by screams of pain. In addition, fever and bilious vomiting existed, together with intense thirst, and as the sharp pain which had been complained of in the right ear four months previously had returned since a week, it was obvious that the otitis had recurred, or that secondary meningitis had set in. Now, a relapse of acute otitis in the same ear is very unusual, and uncomplicated otitis seldom gives rise to coma and vomiting, symptoms which belong more commonly to meningeal irritation. In addition, opium, the chloroform liniment, and leeching had given no relief, and the persistency of delirium alternating with drowsiness, the gradual increase of the facial paralysis, and the typhoid aspect of the countenance left no room for doubt as to the presence of meningitis.

In the course of the fifth day, the child died without convulsions, and the absence of convulsions as well as the rapidity of death confirmed the surmise that no tubercular complication existed, as it is a well known fact that in tubercular meningitis the patient generally lingers for three weeks or more, and convulsions almost invariably set in before death. On dissection it was further ascertained that no tubercular, herpetic, or scrofulous complications existed, and that the case was a genuine instance of simple meningitis consequent on inflammation of the ear.

This fatal issue is, fortunately seldom the result of otitis; but the practitioner should be aware that a disease usually unimportant may in exceptional cases assume the most formidable proportions. In children, otitis is a very frequent

affection, and is, in general, the result of exposure to cold; it may also be connected with measles or scarlatina, and its symptoms differ according to the constitution and state of the system of the subjects.

Danger is not to be apprehended from deep-seated otitis only. Serious complications have been observed in superficial inflammations of the outer ear. Toynbee relates a case in which death resulted from meningitis consequent on acute otitis, and in which, on dissection, nothing was discovered beyond hyperæmia of the petrous bone and detachment of the dura-mater by a serous fluid. Even when the structure of the temporal bone remains unchanged, inflammation of the external ear may induce fatal results, the irritation being then conveyed to the cerebrum by means of the vascular communications existing between the auditory duct, the diploë, and sinuses.

Our space does not admit of our descanting on the affinity of the meningeal symptoms with their cause in the case of internal otitis. M. Roger views them as the consequence of disease of the ear, although several authors hold a contrary opinion.

With regard to treatment, we may remark that the method usually adopted is avowedly unavailing. Although these measures are merely palliative, they must however be resorted to, in order to allay the pain, and subdue, if possible, the gravity of the symptoms. In primary meningitis, it is, of course, necessary to institute powerful antiphlogistic treatment, but in weak children, affected with symptomatic meningeal irritation, depletion should be much more cautiously ventured on.

MEDICAL NEWS.

ROYAL COLLEGES OF SURGEONS OF ENGLAND.—The following Members of the College, having undergone the necessary examinations for the Fellowship on the 21st and 22nd ult., were reported to have acquitted themselves to the satisfaction of the Court of Examiners, and at a meeting of the Council on the 14th inst., were admitted Fellows of the College:—James Vincent Bell, M.D. St. Andrew's, L.R.C.P., High st., Rochester, diploma of membership dated April 11, 1861; John James, Princes street, Leicester square, July 26, 1847; Henry Thomas Lanchester, M.D. Lond., George street, Croydon, April 16, 1861; Ebenezer Ludlow, M.B. Lond., Royal Infirmary, Bristol, May 7, 1862; Alexander Mason MacDougal, L.R.C.P., Bernard street, Russell square, April 29, 1857; Robert Mason, Thomas street, Woolwich, Feb. 11, 1848; James Earl Moreton, Tarvin, near Chester, April 11, 1853; Henry Sacheverel Edward Schroeder, Army, July 26, 1852; William Johnson Smith, Wisbeach, May 9, 1862; Joseph Williams, Brentford, Feb. 27, 1857.

The next examination for the Fellowship will take place in May, 1866.

There will be a Preliminary Examination in Arts for the diploma of Member next week.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH.—At the November sittings of the Examiners in general education of the above Colleges, the following gentlemen obtained certificates of having passed the preliminary examination in General Education. Those marked * gave in papers of superior merit:—Joseph F. W. Brass, Kirkwall; Archibald Campbell, Perthshire; J. Bremner Crole, Edinburgh; John Kerr Davidson, Wick; John Gillies, Isle of Skye; Archibald Grieve, Langholm; Peter Gowan, Markinch; *Joseph Higham, Glasgow; James Hunter, Peebles; John Gulland Hunter, India; Christopher Jackson, Jamaica; R. A. Jackson, Lancaster; John Lennon, Glasgow; John W. Macdonald, Nova Scotia; David M'Lean, Nova Scotia; Donald Malcolm, Wick; William Jones Morris, Liverpool; Francis Cobham Nicholson, Australia; William Agar Renshaw, Lancashire; William Riley, Warwickshire; *Edward Smith, Arbroath; John A. Sutherland, Wick; Josiah Williams, Swansea.

DEATH.

WING.—On the 15th inst., Edwin Wing, M.D., late Resident Physician Superindent of the General Lunatic Asylum, Northampton, aged forty-seven.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, DEC. 27.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1½ p.m.; St. Bartholomew's Hospital, 1½ p.m.; St. Thomas's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, DEC. 28.—*Operations* at the Central London Ophthalmic Hospital, 1 p.m.; St. George's Hospital, 1 p.m.; London Surgical Home, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Institution, 3 p.m.—Prof. Tyndall, "On Sound." (Juvenile Lectures.)

FRIDAY, DEC. 29.—*Operations* at the Westminster Ophthalmic Hospital, 1½ p.m.; Royal Institution, 3 p.m.—Prof. Tyndall, "On Sound." (Juvenile Lectures.)

SATURDAY, DEC. 30.—*Operations* at St. Thomas's Hospital, 9½ a.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-Cross Hospital, 2 p.m.

MONDAY, JAN. 1.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m,; Metropolitan Free Hospital, 2 p.m.

TUESDAY, JAN. 2.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

On Wakefulness. By W. A. Hammond, M.D. Philadelphia: J. B. Lippincott and Co.

"Who Wins." Being the Autobiography of S. B. Carlingford, M.D. Second edition. London: Simpkin and Co., and Hamilton, Adams, and Co.

NOTICES TO CORRESPONDENTS.

It is requested that all communications intended for the Editor may be sent to the Office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office BEFORE NOON on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-Cross Post-office.

CORRESPONDENTS are requested to direct their letters as heretofore to the Office, 20 King William street, Strand, where also all parcels, books for review, and other communications will be received.

CHIRON.—He can recover in a Medical case, but not in a surgical one, unless he possesses the diploma of a College of Surgeons.

ANTI-QUACKERY.—The pamphlet entitled 'Revelations of Quacks and Quackery,' now that it is deprived of its anonymous character, is NO LONGER published at our Office. To append the Author's name is a breach of the understanding with which the Papers were admitted into the columns of this Journal, and we cannot be held responsible for any Addenda which in the pamphlet the Author may choose to make to his papers collated from the Journal. Your question will be brought to the notice of the Anti-Quackery Association.

MR. W. PROWSE'S letter is inserted.

OXONIENSIS.—The letter is inserted.

MR. RICHARD GRIFFIN.—The letter is inserted.

MR. GODFREY.—The announcement is inserted.

N. M.—The subject shall be noticed.
